Mr. Isaac Brown presents his compliments to Dr. Kidd. He cannot but feel flattered that a scientific (!) worker of twenty years should take notice of any communication from so humble an individual as himself. At the same time, while thanking Dr. Kidd for the specimen pages of his book on chloroform, Mr. Brown regrets that a perusal of them has not at all led him to adopt Dr. Kidd's *naïve* suggestion that he should purchase the volume. On the contrary, having read them, and also Dr. Sansom's work on the same subject, he is confirmed in his original belief, that Dr. Sansom is "without doubt next to Dr. Snow, the English physician, to whom we owe most for really invaluable investigations on the subject." This impression is still further strengthened by the fact, to which allusion is made by Dr. Kidd, that Mr. Brown has been in Anstralia, and in no portion which he has visited of that vast territory has he ever heard even mentioned the name of Dr. Kidd.

Mr. Brown finds *no allusion whatever*, in the abstract of his paper as published in the PRESS, *nor did he make any* to the "Surgical Home," as to his father's opinions on the relative value of Dr. Kidd and Dr. Sansom as administrators of chloroform.

Finally, as totally foreign to the subject, Mr. Brown declines to take notice of Dr. Kidd's opinion on "domestic" questions. He is in fact as indifferent on this point as on the matter of Dr. Kidd's unrequited scientific services. In this opinion he believes those who may take the trouble to think at all about the subject will fully agree.

Mr. Brown intends forwarding these letters for publication in the MEDICAL PRESS AND CIRCULAR.

Charles Kidd, Esq., M.D.

[If Mr. Isaac Brown was as well acquainted with Dr. Kidd's calligraphy as we are, he would not have asked us to immortalize that gentleman's style of argument. The space is not lost in the amusement which the correspondence will afford our readers. Ed. M. P. & C.]

### MEDICAL BENEVOLENCE AND COLLEGE DISTINCTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the election of Council and Officers at the Royal College of Surgeons is now approaching, it seems but just and reasonable, that in deciding whom to support, the Fellows may, *ceteris paribus*, allow themselves to be influenced in favour of such candidates as are supporters of the Medical Benevolent Fund—a society that receives the fullest countenance from the two great medical bodies in Ireland, and whose principles must commend it to the support of every physician and surgeon in this country, who has a heart to feel for the difficulties, the distresses, and the sorrows of his poor professional brethren.—I am, sir, yours, &c.,

SUUM CUQUE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I get the credit of being one of the parties canvassing for Dr. O'Sullivan's situation before it is vacant, I have denied it, as you will see by the *Limerick Chronicle* which I send.—I am, sir, your obedient servant,

GEORGE INGLIS, L.R.C.P.E., L.R.C.S.E., L.A.H.I., &c.

## Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners, on the 14th and 15th inst., and when eligible will be admitted to the pass examination:—

Messrs. Daniel George Rowlands, William Inglis Mason, Francis Day Atkins, James Cross, and William Butler, students of Guy's Hospital; James Williams Danahor, Charles John Jones, Henry Worsley, and Ellis Henry Ellis, of the Dublin School; William Agar Renshaw, Handel Ashworth, and Henry Davies Crighton, of the Manchester School; George Bolton, Thomas Benson, and George Rowell, of the Newcastle School; George Harrison Evans, Richard Nightingale Broughton, and William John Noel Bell, of St. Bartholomew's Hospital; Samuel James Davidson and William Hodgson, of University College; Edmund Williams Yorath, of Charing-cross Hospital; John

Rowland Wright, of St. Mary's Hospital; William Edward Bailie, of the Middlesex Hospital; Alfred John Crespi, of the Birmingham School; Charles Henry Beardshaw, of the Leeds School; Charles McCann, Thomas Henry Colman, and Ferdinand Braddles, students of the Westminster Hospital; Ebenezer Nicholas, and Charles Mead, of St. Bartholomew's Hospital; Robert Wilkinson, and George Brack Johnson, of the Newcastle School; John Thomas Redmayne, of Guy's Hospital; George Woodward, of St. George's Hospital; Henry Wotton, of Edinburgh; and Matthew Lorenz Bartholomewsz, of Calcutta and Edinburgh. Twenty-one candidates out of the fifty-seven who presented themselves were referred to their studies for the period of three months.

**MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.**—A Special Meeting will be held on Wednesday, May 22nd, 1867, "For the consideration of the Recent Epidemic," of the form of disease commonly known as black death. Chair to be taken at half-past eight, P.M.

**RAW PORK.**—The *Springfield* (Massachusetts) *Republican* gives an account of six cases of trichinae in a family in that town, caused by partaking of uncooked ham. A few days afterwards the symptoms of disease began to appear—pain and swelling of the eyes, pains in the stomach and bowels, vomiting and diarrhoea, and profuse perspiration. Afterwards the limbs became rigid, the least movement causing great agony. One of the daughters, seventeen years of age, died after a fortnight's illness. She could only lie with her lower limbs perfectly straight, the least change from that position causing her dreadful suffering. During all her illness her pulse was never slower than 130 to 140 a minute, while during the last four days it was too quick to be counted. During the first part of that time her hands and feet were cold and clammy, while the rest of her body retained its natural warmth. On a small piece of muscle examined *post-mortem* trichinae were found at the rate of from 50,000 to 80,000 per square inch. The rest of the family are all getting well, except the mother, whose state is described as still critical.

**WEAPONS OF WAR.**—The firing of the Chassepot rifle has astonished the Emperor of the French by its destructiveness. In two minutes a battalion of 500 men, at 600 yards from the mark, had fired 8,000 balls, of which 1,992 had struck the line of aim. The ground in front of the mark was so cut up that not a blade of grass could be seen; and the Emperor, perhaps, having in his mind's eye 500 Prussians standing in that dangerous spot, is reported to have exclaimed, "It is frightful! It is a massacre!" The Steinheil cannon is also said to be a success. This mysterious weapon, smokeless and noiseless, is based on the application of centrifugal force. The balls are propelled by the motion of a circular disc, traversing a groove from its centre to its periphery, whence they pass through the barrel of the gun. It is merely a scientific application of the weapon with which David killed the gigantic Philistine. Just as a stone, whirled round and round in a school-boy's sling, leaves it with enormous velocity, so this rotatory disc propels cannon balls with enormous momentum. A German artilleryist has made cannon on the same principle, but with four barrels instead of one. There is something curious in this return to first principles. Our steam-rans are reproducing on a mightier scale the beaked galleys of Athens. Even steam itself is sometimes superseded—Ericsson, the famous Swedish engineer, having invented for the narrow sea-channels of his native country gunboats which are worked by the motive power of men. And now power is to be beaten out of the field by the very earliest and simplest form of centrifugal propulsion. The reporter of these marvels thinks he is not too sanguine in entertaining a hope that war will become more and more rare, owing to the dreadful perfection of the instruments intended to further it. An amiable idea, which we have seen expressed pretty often before. But when is it to be realized? So long as humanity remains what it is, there must be sometimes war, though the perfection of weapons tends to make it short, sharp, and decisive. If war ever ceases in Europe it will be due to other causes—to a closer alliance of nations; to a federation so intimate that for France to quarrel with Prussia would be as absurd as for Middlesex to make war on Surrey. Such a state of affairs, though remote, is not impossible.—*Globe*.

#### NOTICES TO CORRESPONDENTS.

*Enquirer.*—Will any correspondent say whether the external use of castor-oil, as an embrocation, is likely to cause a slight feeling of nausea similar to that experienced after taking the oil internally?

*Dr. Croft, St. John's Wood.*—Your paper shall appear in our next.  
*Mr. Harry Lobb.*—Owing to great pressure on our space, we are again compelled to postpone your valuable communication. Proofs shall be sent you.

*Dr. F.*—Our rule is to have proofs returned to the office by Saturday, if the contributions are intended for the next issue.

*Mr. F. J. B.*—Sorry we cannot accommodate you. The topic is worn threadbare, and we do not think any good would come from a discussion in our columns.

*Dr. M.*—You are perfectly right in your surmising of the journal in question.

*Mr. R. O.* is thanked for his prompt reply.

*Hy. H.*—The valuable library of the late John Hewson, F.R.C.S., was sold by auction, at Messrs. Puttick's Rooms, on Tuesday.

*Dr. C.*—Your letter arrived too late for substitution.

*Dr. A. Lane, Colerains.*—Your wishes have received immediate attention.

#### TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Would you kindly inform me why the doses of the spirits of chloroform and of the compound tincture of chloroform, in the new "Pharmacopoeia," are the same—the former being one part in twenty, the latter two in twenty.—Yours obediently,  
INQUISITOR.

[Our Correspondent will observe that we have directed attention, in our remarks on the "Pharmacopoeia," to the absurd inconsistency in the doses of the preparations of chloroform. We are surprised to find that the highest authority in the profession sanctions a method of regulating the dose, founded on fancy and empiricism, rather than that dictated by proper attention to the relative quantities of the active ingredient, which enter into the several preparations of a drug.—Ed. M. P. & C.]

#### MEDICAL VACANCIES.

Halifax Infirmary—Assistant House-Surgeon.  
Rye Union—Medical Officer.  
Township of Toxteth-park—Assistant Medical Officer for the Work-house.  
Wandsworth House of Correction—Surgeon.  
West Kent General Hospital—Resident House-Surgeon.  
Newport Union—Achill Dispensary District—Medical Officer. Salary, £50 a-year.  
Lurgan Union—Tartaraghan Dispensary District—Medical Officer. Salary, £80; Fees, £40.

#### BOOKS, &c., RECEIVED.

On Happiness, in its Relations to Work and Knowledge. Second Edition. By the late Sir John Forbes, M.D.

The Sea-side Register.  
The Principles of Aesthetic Medicine. By Joseph Peel Callow, M.R.C.S.

Chemical Notes for the Lecture Room. By Dr. Wood, T.C.D.

On the Management of Labour in Contracted Pelvis. By William H. Jones, M.D., M.R.C.S.

Archives of Medicine. Vol. IV. Edited by Lionel S. Beale, F.R.S.

New York Medical Journal.

Journal de Médecine et de Chirurgie.

Appendix to the Eighteenth Annual Report of the Prudential Assurance Company.

The Medical Remembrancer, or Book of Emergencies. Fifth Edition.

By Jonathan Hutchinson, F.R.C.S.

On a New Process for Preparing Meat for Weak Stomachs. By W. Marcel, M.D., F.R.S.

## Births, Marriages, and Deaths.

#### BIRTHS.

WHITING.—On the 3rd inst., at Croydon, the wife of H. Townsend Whiting, M.R.C.S., of a daughter.

HARDESTA.—On the 5th inst., High-street, Lochee, Dundee, the wife of J. Jeffrey Hardesty, L.R.C.P. & S. Ed., of a daughter.

LEE.—On the 9th inst., at Watford, the wife of W. Lees, M.D., of a daughter.

MARSHALL.—On the 9th inst., at Mitcham, the wife of E. Marshall, M.R.C.S.E., of a son.

FOWLER.—On the 9th inst., at Kennington-park, the wife of Dr. Fowler, of a son.

BROWNE.—On the 9th inst., at Camberwell-grove, the wife of C. Browne, Surgeon, of a daughter.

NEWMAN.—On the 12th inst., at St. Martin's, Stamford, the wife of Wm. Newman, M.D., of a son.

#### MARRIAGES.

MELDON—RYAN.—On May 15th, at Anne's-street Church, Dr. Austin Meldon, fourth son of James Dillon Meldon, Esq., Casino, Milltown, to Margaret, eldest daughter of the late Patrick Ryan, Esq., J.P., of Seaview House, Ballyard, Tralee.

BURY—COOPER.—On the 30th ult., at Wincanton, Geo. Wm. Fleetwood Bury, F.R.C.S.E., of Whetstone, Middlesex, to Mary Florence, daughter of E. Y. Cooper, Esq.

GOLDSMITH—ROBINSON.—On the 30th ult., at the Parish Church of St. Marylebone, John Goldsmith, M.D., of Worthing, to Sophia Elizabeth Rowden, daughter of the Rev. F. Robinson.

HOOPER—DYER.—At All Saints', Upper Norwood, John Harward Hooper, M.S., F.R.C.S., to Anne, eldest daughter of the late Samuel Dyer, Esq., of Cronhall, Gloucestershire.

#### DEATHS.

TRAEER.—On the 23rd ult., in Paris, J. R. Traeer, F.R.C.S.E., of Hans-place, Sloane-street, aged 34.

HANDS.—On the 28th ult., F. Hands, Surgeon, of Berkeley, Gloucestershire, aged 70.

BLACK.—On the 30th ult., J. Black, M.D., of George-square, Edinburgh, formerly of Bolton-je-Moors, aged 79.

WESTCOTE.—On the 1st inst., T. P. Westcote, L.S.A.L., of Martock, Somersetshire, aged 69.

## Lecture.

## THE METROPOLITAN WATER SUPPLY.

## A DISCOURSE

DELIVERED AT THE

ROYAL INSTITUTION OF GREAT BRITAIN,

MARCH 29TH, 1867.

By Dr. E. FRANKLAND, F.R.S.

PROFESSOR OF CHEMISTRY IN THE ROYAL INSTITUTION.

(Continued from page 479.)

The organic matters containing nitrogen which occur, dissolved in water, are chiefly, if not entirely, of animal origin, being derived either from sewage or manured land; be their origin, however, animal or vegetable, no distinction, founded upon their source, can be drawn between their respective noxious qualities. After admixture with spring or river water, these noxious organic matters undergo slow oxidation, by which they are finally resolved into comparatively innocuous mineral compounds; their carbon is converted into carbonic acid, and their hydrogen into water, and these products can no longer be identified in the aerated waters of the river or spring; but the nitrogen is converted into nitrous and nitric acids, which, combining with the bases contained in most waters, remain dissolved, and constitute a record of the sewage or other analogous contamination to which the water has been subjected. With certain corrections presently to be mentioned, the analytical determination of the nitrogen contained in these salts, and in the form of ammonia, writes, as it were, the history of the water as regards its contact with decomposing animal matter. Such *previous organic contamination* may be conveniently expressed in parts of average filtered London sewage, which, if thus completely oxidized in a river, would yield a like amount of nitrogen in the form of nitrites, nitrates, and ammonia. For this purpose, average filtered London sewage may be taken as containing 10 parts of combined nitrogen in 100,000 parts, as deduced from the numerous analyses of Way, Hofmann, and Witt. The number so obtained as the *previous sewage contamination* of a water requires, however, a correction, since rain water itself contains combined nitrogen, as ammonia, nitrite of ammonia, and nitrate of ammonia. The amount of these substances present in rain which falls at Rothampstead has been most carefully determined by a laborious series of monthly analyses, made independently on the one hand by Messrs. Lawes and Gilbert, and on the other by Professor Way, and extending over two years. The results of these chemists accord well, and they give as the average amount of nitrogen in the forms of ammonia, nitrite of ammonia, and nitrate of ammonia, 0.985 part in 100,000 parts of rain water. This must be deducted, therefore, from the calculated amount of previous sewage contamination of any sample of water. It corresponds to 985 parts of previous sewage contamination in 100,000 parts of the water. There is no doubt that this reduction is too large, and therefore favourable to the character of the water, since, in most cases, but a very small proportion of the water of a river or spring falls as rain directly into the stream, and Professor Way has proved that almost every trace of the ammonia contained in rain water is absorbed when the water percolates through cultivated soils. Now, as three-fourths of the combined nitrogen in rain water is in the form of ammonia, it is evident that rain water must be deprived of much of its original nitrogenous contamination before it reaches such a river as the Thames. The very small amount of combined nitrogen found in natural waters of undoubted purity, such as that of Loch Katrine, for instance, also testifies to the liberality of the above allowance. The water of Loch Katrine contains only one-third as much combined nitrogen as that present in rain falling at Rothampstead, so that, starting from the base-line of purity

above proposed, the water of Loch Katrine exhibits a *negative* previous sewage contamination equal to 575 parts in 100,000; or, in other words, it would require 575 parts of average London sewage to be added to, and allowed to oxidize in, each 100,000 parts of Loch Katrine water before its purity would be reduced to the standard with which I propose to compare the metropolitan waters. It is necessary here to remark, however, that, owing to the more copious rains of the Highlands of Scotland, the rain water of that district probably contains less combined nitrogen than that which falls at Rothampstead.

The nitrogenous organic matter which has escaped the process of oxidation above described, and which, therefore, still exists in the water at the time the analysis is made, constitutes what may be appropriately termed the *present sewage contamination* of the water. The existence of this contamination is shown by the presence of organic nitrogen in the water, and its amount may be expressed by the number of parts of average filtered London sewage (of the strength above described), which, if contained in 100,000 parts of pure water, would contaminate the latter with the same amount of combined nitrogen. By operating upon one litre of water for the determination of total combined nitrogen, one per cent. of sewage can be detected with certainty, but smaller percentages ought, in operations upon such a small quantity of water, to be considered as falling within the possible errors of experiment. Thus, in the table of analytical results given below, the indications of organic nitrogen, and consequently of present sewage contamination, amounting in the maximum to one-half per cent., ought to be disregarded, because, as the total combined nitrogen was determined in one litre of each water, the amount of present sewage contamination indicated by the analysis falls within the limit of possible experimental error. The subjoined tabulated results obtained in the analysis of samples of the metropolitan waters collected in February last, and during the present month, show, therefore, that none of these waters contained as much as one per cent. of present sewage contamination. This search for unoxidised sewage, or its equivalent, in a water, may be rendered more minute by operating upon a larger volume of water, by which the possible error of experiment is reduced in proportional amount. Thus, if 10 litres of water be used for the determination of total combined nitrogen, one-tenth of a percent of present sewage contamination can be ascertained with certainty. This operation has been performed upon 10 litres of the Thames water delivered by the Grand Junction Company, and collected during the present month; and it is satisfactory to find that this minute examination failed to detect any actual sewage contamination, consequently it is certain that the sample of the Grand Junction Company's water operated upon did not contain 1-1000th of its volume of unoxidised sewage. It must be consolatory to the drinker of Thames water to know that although, according to Mr. Bateman, the population within the basin of the Thames above the points at which the water is withdrawn for the supply of London exceeds 1,000,000 persons, the drainage of some 600,000 of whom is poured into the river, the whole of this fœcal matter is so completely oxidised before it reaches the water cisterns of London, as to defy the detection of any trace in its noxious or unoxidised condition. If the average flow of Thames water, just above the point at which the London companies withdraw their supply, be taken at 800,000,000 of gallons daily, the drainage of 600,000 people ought to produce a sewage contamination of 2250 parts in 100,000. It could scarcely be expected that this calculated number should approximate very closely to that obtained by the actual analysis of Thames water, since the calculated number depends upon many contingencies, as, for instance, upon the volume of water actually flowing past the points of withdrawal at the time the Companies abstracted the water analyzed; and secondly, upon the greater or less retention of the fœcal matters in the sewers of the towns draining into the river. It is interesting, however, to find that the sewage contamination of Thames water, as deter-

mined by analysis, does not differ much from that calculated according to the above data. The analytical table given below shows that the average previous sewage contamination of the water delivered by the five companies drawing their supply from the Thames during the months of February and March, 1867, was 2466 parts in 100,000 of water, the amount calculated from the number of persons draining into the river being, as just mentioned, 2250 parts in 100,000 of water. As summer advances, and aquatic vegetation becomes vigorous in the bed of the Thames and its tributaries, this coincidence of calculated and analytical results will probably be disturbed, as the water-plants can scarcely fail to withdraw an appreciable amount of nitrates and nitrites from the water, thus diminishing the quantity of combined nitrogen, and consequently of previous sewage contamination, as determined by analysis.

The second important class of impurities contained in water used for domestic purposes consists, as above-mentioned, of certain mineral salts which possess the power of decomposing soap. These substances are the hardening or soap-destroying constituents of waters. From a purely sanitary point of view they are of less direct importance than the organic impurities; still, by rendering efficient ablation and thorough cleanliness difficult of attainment, they doubtless indirectly affect the health of communities supplied with waters in which they are present in considerable quantities. The chief hardening ingredients in potable waters are the salts of lime and magnesia. These salts decompose soap: forming curdy and insoluble compounds containing the fatty acids of the soap, and the lime and magnesia of the salts.

So long as this decomposition goes on, the soap fails to produce a frothiness in the water, but when all the lime and magnesia salts have been decomposed by the action of the soap, the slightest further addition of the latter produces a lather when the water is agitated, but this lather is again destroyed by the addition of a further quantity of the hard water. Thus, the addition of hard water to a solution of soap—or the reverse of this operation—causes the production of the insoluble curdy matter above mentioned. Bearing this in mind, it is easy to understand the process of washing the skin with soap and hard water, which may be thus described:—First, the skin is wetted with the water, then soap is applied; the latter soon decomposes all the hardening salts contained in the small quantity of water with which the skin is wetted, and there is then formed a strong solution of soap which penetrates into the pores of the skin. This is the process which goes on whilst a lather is being produced in washing, but now the lather requires to be removed from the skin. How can this be done? Obviously, only, in one of two ways—viz., by wiping it off with a towel, or by rinsing it away with water. In the former case the pores of the skin are left filled with soap solution; in the latter they become plugged up with the greasy, curdy matter which results from the action of the hard water upon the soap solution occupying the pores of the cuticle. As the latter process of removing the lather is the one universally adopted, the operation of washing with soap and hard water is perfectly analogous to that used by the dyer or calico-printer when he wishes to fix a pigment in the pores of any tissue. He first introduces into the tubes of the fibre of calico, for instance, a liquid containing one of the ingredients necessary for the formation of the insoluble pigment; this is followed by another liquid containing the remaining necessary ingredients; the insoluble pigment is then produced within the very tubes of the cotton fibre, and is thus imprisoned in such a manner as to defy removal by subsequent washing. The process of ablation, therefore, in hard water, is essentially one of dyeing the skin with the white, insoluble, greasy and curdy salts of the fatty acids contained in soap. The pores of the skin are thus blocked up, and it is only because the insoluble pigment produced is white that such a repulsive operation is tolerated. To those, however, who have been accustomed to wash in soft water, the abnormal condition of the skin thus induced is, for a long time, extremely unpleasant.

Nevertheless, opinion is not quite unanimous as to the advantages of soft water over hard. Some persons consider hard water to be necessary for the supply of the calcareous matter of the bones; others believe soft water to be peculiarly liable to attack and dissolve the lead of the pipes through which it is conveyed, or of the cisterns in which it is stored. An examination of the grounds upon which these opinions are based, would completely refute them; but the limits of this discourse do not permit of such a digression, and I must therefore content myself with a mere allusion to one or two facts in connection with them. First, as to the necessity of hard water for the supply of the calcareous matter of bones. If it be assumed that a man drinks daily half-a-gallon of Thames water he obtains from it  $3\frac{1}{4}$  grains of lime, chiefly in the form of chalk. This amounts to not quite three ounces per annum, which does not seem to be a very large contribution to bony matter. Now, suppose the use of this water to be discontinued, and that no part of it is replaced by bitter beer, which always contains far more lime in a given volume than Thames water; but we will assume that the individual consumes one-third of a pint of milk per day, in this quantity of milk he receives more lime than his system acquires from two quarts of Thames water. Then as to soft water attacking and dissolving lead; it is by no means true, as a general proposition, that soft water does attack and dissolve this metal. The very soft water of Loch Ness as supplied to Inverness does not attack lead, as evinced by the condition of the lead pipes which I now produce, and through some of which that water flowed for six years; neither does the soft water of Emerald Lake supplied to Whitehaven attack lead. Even those soft waters which do attack the metal, such as those now supplied to Glasgow and Manchester, only do so when the surface of the lead is clean and bright. The action soon ceases, in fact as soon as the metal becomes tarnished the pipes are protected, and no complaints of any symptoms of lead poisoning have for the past ten years been heard from these large cities. Lastly, a sample of very soft water taken from one of the principal streams from which it is proposed to supply London, has no action even upon clean and bright lead. Notwithstanding the numerous researches made in connection with this subject, the causes of the attack of lead by water have not yet been completely elucidated; it has, however, been established that the presence of oxygen and the comparative absence of carbonic acid in the dissolved gases are essential conditions to this action. Messrs Graham, Miller, and Hofmann, in their report on the Metropolitan Waters in 1851, first showed that carbonic acid, when dissolved in water, was a complete protection against lead contamination, and from a series of experiments recently made I find that two volumes of carbonic acid dissolved in 100 volumes of water completely protect even distilled water from such contamination. Rain water as it descends to the earth dissolves atmospheric gases, and this solution is afterwards continued in brooks and rivers. Of the chief atmospheric gases carbonic acid is by far the most soluble, 100 volumes of pure water can dissolve 100 volumes of this gas; oxygen, on the other hand, only dissolves to the extent of three volumes in 100 volumes of water. Nevertheless, owing to the much larger proportion of oxygen than of carbonic acid in atmospheric air (500 : 1), water takes up oxygen more rapidly than carbonic acid, and hence freshly fallen rain water acts upon lead, but when the water flows a great distance through an open conduit, the carbonic acid absorbed finally reaches the protecting proportion, and the action upon lead ceases, although the water retains its original softness. Hence there is no necessary connection between soft water and lead corrosion. Even distilled water left in contact with the air for some time loses its property of acting upon lead.

The third class of impurities present in potable waters, viz., matters which are not expelled at a red heat, and which do not decompose soap, require no detailed notice; they consist chiefly of salts of the alkali metals, such as the sulphates and chlorides of potassium and sodium. Unless

present in excessive quantity they are innocuous both as regards the internal and external use of the water.

We are now in a position to understand the following

table which contains the results of the analytical examination of the waters supplied to the metropolis during the past two months :—

QUALITY OF THE WATERS SUPPLIED TO THE METROPOLIS DURING THE MONTHS OF FEBRUARY AND MARCH, 1867.

1 Names of Companies.	2 Total solid impurity in 100,000 parts of water.		3 Organic Carbon.		4 Nitrogen as Nitrates and Nitrites.		5 Ammonia.		6 Total combined nitrogen.		7 Previous sewage contamination.		8 Hardness.		9 Soap destroyed.

Water from Loch Katrine as supplied in Glasgow.....	3'28	...	'256	...	'031	...	'002	...	'041	...	0	...	'3	...	3'6	...

The numbers in columns 2, 3, 4, 5, 6, 7, 8, and 9, all relate to 100,000 parts of the waters. Column No. 2 shows the total solid impurity contained in each water, as delivered from the Company's mains. No. 3 gives the amount of carbon contained in the organic matter present in this solid impurity. No. 4, the amount of nitrogen in the form of salts of nitric and nitrous acids. Column No. 5 shows the amount of ammonia present in each sample, and column No. 6 records the total amount of nitrogen in the several forms of nitrogenous organic matter, salts of nitric and nitrous acids, and ammonia; whilst column No. 7 exhibits the previous sewage contamination, estimated as above described. Column No. 8 shows the hardness of each water as estimated by the soap test—that is, the number of parts of carbonate of lime, or its equivalent of other hardening salts, contained in 100,000 parts of the water. Finally, column No. 9 gives the amount of soap which it is necessary to add to 100,000 parts of each water before a lather can be produced, this amount of soap being thus wasted or destroyed in decomposing the hardening constituents of the water. It is usual to call each part of carbonate of lime or its equivalent of other hardening material in 100,000 parts of water, a *degree of hardness*.\* Each degree of hardness indicates the destruction of 12 parts of the best hard soap by 100,000 parts of water.

As an example of the mode of reading the above table, we may take the Chelsea Company's water, 100,000 lbs. of which contained, in the month of February last, 28'58 lbs. of solid impurity; the organic matter constituting a portion of this impurity contained 0'433 lb. of carbon. This solid impurity also contained 0'337 lb. of nitrogen in the shape of nitrates and nitrites, besides 0'004 lb. of ammonia, whilst the total amount of combined nitrogen in every form was found to be 0'371 lb. The above quantity of water, as supplied by the Chelsea Company, had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 2420 lbs. of average London sewage. By gradual oxidation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reservoirs, filters, and conduits of the Chelsea Water Company, this sewage contamination had been entirely converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the said water contained 16'2 lbs. of carbonate of lime, or their equivalent of other hardening ingredients; whilst, if the water were used for washing, 100,000 lbs. of it would occasion the waste of 194'4 lbs. of the best hard soap.

For the purpose of comparison, I have also appended to the above table the results yielded by Loch Katrine water, as delivered in Glasgow, when submitted to the same analytical processes. A glance at the table will show how vastly superior, in all respects, is the quality of this water, as compared with the best at present supplied to London. 100,000 lbs. of this water contain but 3'28 lbs. of solid impurity; it has no sewage contamination, previous or present; and it has only 0'3 degree of hardness, occasioning the destruction of only 3'6 lbs. of soap by 100,000 lbs. of the water.

Such is the chemical history of the water at present supplied to the metropolis, and it must be borne in mind that grave as are its defects, the mode of the delivery of this water to consumers is still more defective. That in a densely-populated city water should be delivered only once, and for a few minutes, in 24 hours, and not at all on Sundays, is a condition of things utterly incompatible with the supply of wholesome and palatable water. Even if the water of Loch Katrine itself were delivered in London, according to the system at present adopted by the metropolitan water companies, it would infallibly be rendered unfit for human consumption after 24 hours of exposure to the vile atmosphere and sewer gases in which the water-cisterns of London are systematically placed.

The fundamental defects of our present water supply may be thus summed up:—

1. Great previous sewage contamination.
2. Liability to present sewage contamination.
3. Great hardness.
4. Intermittent supply.

QUALITY OF THE PROPOSED METROPOLITAN WATER SUPPLY.—The waters from the sources of the Severn and from the Cumberland Lakes have not yet been submitted to the above analytical processes, and it is therefore impossible to compare them in all respects with the present metropolitan supply. The water of the Bala Lake, in North Wales, which may be regarded as similar to that which would be supplied by Mr. Bateman's scheme, has been examined by the late Dr. R. D. Thomson; and the waters of the Cumberland Lakes have been more elaborately investigated by Professor Way. From the analyses of these chemists, the following numbers are calculated:—

	Total solid impurity in 100,000 parts.	Hardness.	Soap destroyed.
Bala Lake.....	2'97	1'0	13'2
Hawes Water ..	5'70	2'0	34'8
Ullswater.....	5'94	3'0	36'0
Thirlmere.....	5'16	2'1	25'2

A comparison of these numbers with those given in the previous table exhibits the great superiority of the proposed waters over those at present supplied to London, as regards total solid impurity and soap-destroying ingredients, whilst

\* The degree of hardness more usually employed by chemists is that first proposed by Dr. T. Clark—viz., one grain of carbonate of lime, or its equivalent, in one Imperial gallon of water, or one part in 70,000 of water. The degrees in the above table harmonize better with the decimal arrangements of the rest of the analytical results. They are readily converted into Clark's degrees by multiplying by 7, and then moving the decimal point one place to the left.

it can scarcely be doubted that waters obtained from such sources will be as free from deleterious organic contamination as that of Loch Katrine.

**AMELIORATION OF PRESENT WATER SUPPLY.**—In the event of a new source of water-supply being at once determined upon, at least seven years must elapse before it can be rendered available to the metropolis, it therefore becomes important to enquire how far it is possible in the interim to ameliorate our present supply. The first and most obvious improvement would be the substitution of the *constant* for the *intermittent* system of delivery. With certain restrictions, all the metropolitan companies express their willingness to make this change, and with the unanimity of opinion regarding its advisability it is difficult to account for the delay in affecting it, unless it arises from the paltry cost involved in the alteration of the present fittings, which would fall upon the landlords of small tenements. Most towns of importance in Great Britain have been long supplied with water on the constant system; why then is this boon denied to London, where it is much more urgently required? Until this alteration is effected, it is, for the bulk of the population, almost useless to improve the quality of the water. Where a supply for one or even two days has to be stored in a filthily butt, exposed to the foul atmosphere of a crowded court or ally, good and wholesome water can never reach the lips of the consumers.

The most formidable danger arising from the use of the present water-supply is undoubtedly the liability to actual sewage contamination, such as that which there is every reason to believe destroyed so many lives in the East of London last summer. How can we best protect ourselves against this noxious contamination? The answer is, there is no absolutely reliable protection. Filtration through animal charcoal is perhaps the best, but I have shown that this process fails to remove from water the matter which is believed to constitute cholera poison. Permanganate of potash is also an excellent purifier of water, but there is not the slightest evidence that this agent can destroy cholera poison. Boiling the water for a short time is no guarantee that its noxious qualities are destroyed, for even on the very probable supposition that cholera and other similar poisons are organic germs, we know that many such germs, especially such as are of a low type, retain their vitality after being boiled in water, or even after exposure to a temperature of 248° F. for a considerable time. The late Dr. Lindley mentions the fact of raspberry seeds germinating after being boiled for jam, and as syrup boils at a considerably higher temperature than water, these seeds must have been exposed to a heat much higher than that of boiling-water. Nearly twenty years ago a curious red fungus or mould (*oidium aurantiacum*) attacked the bread of Paris. M. Payen exposed pieces of bread, upon which spores of the fungus had been sown, for half an hour to 248° F. in tubes, the red fungus afterwards germinated, although its vitality was destroyed when the temperature was raised to 284° F. I have undoubted evidence of the production of violent cramps and diarrhoea by the drinking of tea made from water, which, previous to boiling, had become contaminated with sewage.

Nevertheless, whilst none of these methods can be *relied upon* for the destruction of noxious organic matter in water, I am far from wishing to discourage their use as measures of precaution. More especially would I recommend filtration through animal charcoal as a most undoubted and valuable means of greatly reducing the amount of organic matter in water. I find that water will readily pass through a stratum of animal charcoal, three feet thick, at the rate of 41,472 gallons per day, per square foot, the organic matter contained in the water being reduced to one-half. 500 tons of animal charcoal would be an ample quantity through which thus to pass the whole of the present metropolitan water supply. This, at £13 per ton, would cost £6500. This charcoal would require to be heated to redness in retorts or ovens, for a couple of hours every six months. It would last for two years, and would then be worth nearly half its original cost as manure.

With regard to the excessive hardness of the London waters, it does not appear that any practicable scheme of amelioration can be contrived. Some years ago a beautiful and very simple process of softening hard waters by the addition of lime, was devised by Dr. Clark, of Aberdeen, but, although this process has repeatedly been tried by Water Companies, it has invariably been again abandoned, since, notwithstanding the cheapness of the material employed, the amount of carbonate of lime deposited by the London waters, when submitted to this treatment was, in the case of such vast volumes of water, so enormous as to cause the process to be pronounced impracticable. It is to be feared, therefore, that we must for the present be content to block up the pores of our skins with the greasy curd of hard water, but it is very desirable that the other ameliorations of which I have spoken, should be carried out at once, although they ought not to delay the introduction of a water-supply free from sewage contamination. Such a supply is a priceless boon to a community, and, relying upon our experience in other cities, it is not too much to hope that its introduction into London would be the means of banishing for ever *epidemic cholera* from the capital of this country.

### PARALYSIS: CASES ILLUSTRATIVE OF A NEW METHOD OF TREATING IT BY THE APPLICATION OF COLD OR HEAT ALONG THE SPINE.

By JOHN CHAPMAN, M.D., M.R.C.P.,

PHYSICIAN TO THE FARRINGTON GENERAL DISPENSARY.  
(Read to the Harveian Society of London, April 4, 1867.)

(Continued from p. 433.)

I WILL now advert to two cases of paralysis due to cerebral affections, in the treatment of which the spinal hot water-bag was the chief remedial agent. Full reports of these cases were published in the *Medical Times and Gazette* shortly after their occurrence; the following is an abstract of those reports:—

#### 6.—Case of Apoplexy with Hemiplegia.

On December 3, 1864, I was called to a gentleman, aged 55, whom I found in a state of profound stupor; he could not be roused, the right arm and leg were paralysed, the leg less completely so than the arm. When the hand was pinched severely there was no evidence of sensibility; the left hand was of a markedly dusky hue, the nails being slightly purple; the temperature of the left side was considerably lower than that of the right, and the pulse which was 82, was much feebler at the left than at the right wrist; the head was hot; both eyes were closed, the left one being protruded abnormally and slightly lachrymose; the face was drawn to the left side.

I applied an 8 inch spinal water-bag, containing water at 120° Fahrenheit, to the cervical and upper dorsal region of the spine. This bag was ordered to be refilled at frequent intervals, so that the application of heat might be continuous during the day or whenever the head should be found hotter than natural. A spinal ice-bag was also ordered to be applied at once during three-quarters of an hour to the lower third of the spine, and to be repeated the same afternoon. In less than twenty minutes after the hot-water bag was first applied, the head had become much cooler than before, and within twelve hours some degree of returning consciousness was evinced. The treatment was modified according to symptoms as the case progressed. The patient steadily improved day by day. At the end of a week he was talking with facility; on the 23rd of the next month he walked between one and two miles two days in succession, and in February he called upon me, and reported himself quite well, and impressed me as being so both mentally and physically.

December 3rd, 1865, exactly a year after the date of the above mentioned attack, I was called to this patient again. On the previous day he became suddenly giddy and incapable of standing. Shortly afterwards he vomited and was relieved, but his speech, which was previously perfect, had become much impaired, and immediately before I was summoned he suddenly lost the power of speech, his eyes becoming, as his wife said, "fixed and glassy." Ice was applied to the spine and benefited him considerably. I found him much better again, and his speech, though greatly impaired, was intelligible. I ordered ice to the lumbar region 45 minutes at eight P.M., a saline mixture and light food.

After passing a good night, vomiting came on at 5:30 A.M.; consciousness and the mental faculties were greatly impaired, and the power of speech was so far lost that he was quite unable to make himself understood. Ice was applied at nine A.M., and at ten A.M. I saw him, when he had somewhat improved: he was conscious, and he had recovered his power of speech to a slight extent; but his mind was dull and confused. The face and tongue were drawn to the left side, and both arms were slightly paralysed. Pulse 76, full and fairly strong in the right wrist, extremely slight and feeble in the left. I requested ice to be applied during thirty minutes every two hours, to the lumbar region; and the water bag at 115° Fahr. to the cervico-dorsal region during ten minutes, also every two hours, but alternately with the ice. The saline mixture was continued; and the patient was nourished with beef-tea. In the course of two days he was very greatly improved in all respects; the heat and cold were then applied at more distant intervals, and on the following day (December 7), I found the head clear, the speech fairly recovered, and the pulse in the left wrist much increased in strength and volume. The use of heat was then discontinued; and I requested the ice-bag to be applied along the lower two-thirds of the spine half-an-hour, and the saline mixture to be given three times a-day. By the 21st of the month the patient had quite regained his former health: his mind was clear, his speech distinct and normal; his face symmetrical, and his pulse in the left wrist as strong as that in the right. The medicine was discontinued, and the ice after being applied once daily until the 26th, was left off at the request of the patient, who, at that date, took a long walk alone.

#### 7.—Case of Apoplexy, with Hemiplegia.

On March 14th, 1865, I was called to a patient at Brighton, a stout woman, aged 60, who, in the afternoon of the previous day, being excessively flushed, with a dull, heavy expression, staggered towards her bed and fell down senseless. The physician, who was immediately called in, said she was dying. He stayed with her until three o'clock of the following morning, and, on leaving, sent a woman to "lay her out." As stated by a spectator, "she gasped, seemed to breathe only at intervals, was blue round the mouth, clayey-looking; the whole features seemed to sink; her head, shoulders, arms, and legs were quite cold, and her face was covered with clammy sweat." She remained in this state during forty-eight hours. At the end of this time I visited her. The head and face were strikingly cold and death-like; the eyes exuded a thick gluey fluid; the left pupil was dilated and immovable in the presence of light, the right pupil was contracted; the right side was more dusky, and somewhat colder than the left; the face was drawn to the left side. On tickling the soles of the feet, there was a slight movement of the left foot; none of the right.

In the treatment of this case, my efforts in the first instance were directed to produce alternate contraction and relaxation of the cerebral blood-vessels, in order to effect movement of the stagnant blood within the head. Accordingly, I applied heat on each side of the upper third of the spine for a few minutes, then removed the bag, while still hot, and shortly afterwards re-applied it. Within fifteen minutes of my first application to the spinal region, an area of about two and a-half inches in diameter in the middle of the forehead became quite warm. Before twelve

hours had elapsed, the whole head and face became warm; and within twenty-four hours, or by the evening of the 16th of March, her whole body was warm. On this day she saw a cup of beef-tea in the hands of an attendant, and opened her mouth as if asking for it. The same evening she was believed to have recognised her daughter. From that date she steadily progressed in intelligence, so that by the end of the month she appeared to understand all that was said to her, could appreciate a joke, and could answer questions by monosyllables. She began to gain some power on the paralysed side, and, as the weeks passed, her improvement in intelligence and power of expression gave promise of her ultimate recovery, though, of course, with the probability that she would continue more or less hemiplegic. She lived about three months; but, unhappily, owing in part to the neglect of her nurse, sloughing over the sacrum came on unperceived, pyæmia followed, and proved fatal.

In both these cases the great therapeutical efficacy of the spinal hot-water bag was signally manifested. One of the sons of the first of the two patients, a very intelligent young gentleman, who sat up at night with his father, expressed himself much astonished by the power of the water-bag in reducing the heat of the head, and volunteered the statement that when his father's breathing was stertorous, the application of the bag speedily caused it to become quite tranquil. I may add here that, in the case of a patient under my care, who is liable to become unconscious by reason of a great and sudden afflux of blood to the brain, the application of this bag at a temperature between 115° and 120° Fahrenheit, will invariably cause the hot head to become cool, and simultaneously consciousness returns.

It will be observed that I applied heat to the upper portion of the spine, and cold below, at the same time, in the first of the two cases just reported; and I may add that, in the second case, I often had occasion to do the same. The simultaneous application of heat above and cold below, or the reverse, so far from resulting in the neutralization of the effects of the one by the other, actually augments greatly the force of each. For example, while heat to the upper third of the spine effects the contraction of the cerebral arteries, and so lessens the amount of blood in the brain, cold along the lower third of the spine, by causing the dilatation of the arteries of the pelvis and lower extremities, increases the amount of blood in those parts, and, therefore, to a proportionate extent, derives it from the chest, upper extremities, and brain. Hence, if I wish to exercise only to a moderate extent a sedative influence on the brain, I apply the lumbar ice-bag; but if I wish to act more vigorously, I apply the double-column hot-water bag to the upper third of the spine; if more vigorously still I use the two simultaneously. The two cases just described afford most satisfactory illustrations of the unprecedentedly great remedial power in cases of apoplexy which this method of treatment affords. Of course, the sooner after the "stroke" treatment is adopted, the greater will be its efficacy. My experience, however, enables me to say, that in cases of paralysis of several years standing, great good may often be done by means of these spinal applications. In the appendix to my pamphlet on "The Functional Diseases of Women," I published a case, the chief features of which are as follows:—

#### 8. Case of Chronic Hemiplegia, with rigidity of the left upper extremity, coldness of the paralysed side, headache, dorsal hyperæsthesia, and constipation.

A boy, aged 13, afflicted with hemiplegia (left side), was brought to me June 1, 1863. At this date I made the following notes of his condition:—Has a florid complexion, looks healthy, and is very intelligent. Complains chiefly of being unable to use his left arm. He cannot raise it above his head, as he can the right one—being unable to lift the hand higher than the face. The fore-arm cannot be completely extended, and is firmly fixed in the prone position. The wrist and hand are not only powerfully drawn to the

ulnar side, but so firmly flexed on the fore-arm as to resist whatever extending force the patient can apply with his right hand. If by additional external force they be brought into a straight line with the fore-arm, immediately they are released from it they return to their abnormal position. The metacarpal bone of the thumb is strongly adducted and held (immovably by the patient's will) in the palm of the hand. The four fingers are permanently bent inwards, the middle one being flexed over the end of the thumb and deeply indented by the thumb-nail. The third phalanx of the index finger bends backwards on the application of the slightest pressure, and is incapable of offering any resistance—that fasciculus of the flexor profundus digitorum, which converges into the tendon of this finger, being paralysed. The whole upper extremity of the left side is considerably shorter and smaller than that of the right. The left leg is also shorter and thinner than the right, although the arrest of growth has been less in the leg than in the arm. The patient cannot stand on the left leg, and when he attempts to extend it completely, he feels a stiffness at the top of the calf. If he places the heel on the ground, and then lifts up the fore-part of the foot, it immediately drops—he cannot sustain it. He can bear no weight on the fore-part of the foot, and cannot bend his toes either upwards or downwards, except in a very slight degree. The tendo-Achillis has been divided. The right pupil is slightly the largest; the tongue deviates to the left side. The patient suffers from frequent and long-continued headache, on an average three times a-week; if he gets up with it, it lasts all day. His back is peculiarly sensitive: he bursts into hysterical laughter the moment it is touched. The whole of the left side is habitually cold. Bowels constipated: not opened oftener than every other day. The patient's malady originated, his father says, in a fall on his left side when he was six months old. From this time the elbow was observed to be slightly bent, and the fore-arm always pronated. In his twelfth month the weakness was first noticed in the leg. In his third year he was taken to L'Hospital des Enfants Malades at Paris; then to "a private doctor," who bandaged the arm and hung a weight to it; he subsequently attended the Orthopædic Hospital in London, where, in addition to other treatment, by galvanism, &c., the tendo-Achillis was divided; and, finally, he was a patient during two years at another Metropolitan Hospital.

My treatment of him consisted mainly in the application of ice along the spine, the only other measures adopted were, washing him all over every morning in cold water; clothing him in flannel down to the wrists and ankles; rubbing the back and paralysed side; galvanism as mentioned below; and making frequent efforts to supinate the fore-arm.

The patient's headache ceased from the time the ice was applied. By the 8th of June, the left arm and leg became quite warm; by the 15th, the bowels had become open daily, the preternatural sensitiveness of the back had ceased, and when the left heel was placed on the ground, the fore part of the foot could be held up during at least five minutes.

As early as July 14, the power of the whole left arm, either for movement or lifting objects, had greatly increased; the hand was much less flexed and drawn to the ulnar side than formerly; the metacarpal bone of the thumb, which even a fortnight before needed a good deal of external force to draw it from the palm, could then be abducted by the will of the patient himself; he could open the fingers, and extend them completely; and the third phalanx of the index finger, formerly paralysed, he could flex strongly. His left leg also continued to grow stronger: he could stand alone upon it without support for a considerable time; the stiffness formerly felt at the top of the calf, when he attempted to extend it, was completely gone; he could hold up the fore part of the foot when the heel was on the ground as long as he liked; he could move the toes, especially upwards, much more freely, and, as he said, he walked "much better" than formerly. I ordered the extensor muscles of the fore-arm, especially those of the thumb, to be galvanized frequently; the treatment in other respects to continue the same.

The last record which I made of this case was July 28, and was as follows:—When the hand is in a passive state it is now quite straight in relation to the fore-arm, and its grasping power is notably increased. The patient can walk on either the heel or toes of the left foot, and in ascending stairs can bear all his weight so completely on his left toes, as to be able to go up by advancing each foot a step alternately. The bowels continue to be opened daily; the left side continues remarkably warm, and during the two months of treatment headache has never been felt.

As the radial side of the fore-arm has been turned inwards ever since infancy, it is probably held in that position, not only by the pronator muscles, but by adherent tissue developed between the immobile structures. Holding this opinion, I directed the boy to make continuous efforts forcibly to supinate the fore-arm, and already the rotating power has increased. If his left tendo-Achillis had not been divided, he would now walk, I believe, with only such a slightly perceptible limp as would be due to the difference in length of the two legs; there is more unevenness in his gait than that difference will account for, and I ascribe it to the operation which he underwent. Indeed, he could walk better, he says, before the operation than afterwards; and he is probably right, for he also says that before the operation the muscles of the calf were fully developed, whereas afterwards they gradually wasted.

As in the treatment of cases of paralysis of long standing medicines are, notoriously, of slight avail, and as any merely theoretical considerations which I may advance in favour of the method I am advocating will not be likely to exert much influence, I shall, I hope, be permitted to adduce, as evidence in support of that method, the reports of two other cases which were published in the *Journal of Mental Science*.

9.—*Case of Hemiplegia, with persistent headache; impairment of intelligence and vision; obstinate constipation; and deficient expulsive power of the bladder.*

H. D. J.—, suffering from hemiplegia, consulted me, August, 12th, 1863. He can lift the right elbow nearly as high as the shoulder, when the arm is flexed; but when extended, only as high as the mamma. The supra-spinatus muscle of the right side is considerably wasted. Can flex the fore-arm vigorously, but can extend it only imperfectly and feebly. Can flex the fingers and thumb closely, but not powerfully; cannot extend the fingers beyond a right angle with the palm; cannot extend the thumb. Cannot stand on the right leg without support; it is not wasted. Cannot extend the toes except very slightly; can flex them better, but much less than he can the toes of the left foot. The right foot and leg, as high as the knee inclusive, are habitually cold; so cold that even now he has a fire every night to warm them before going to bed. Drags his left foot, and wears the toe of his shoe out in consequence.

Has continuous pain on the right side of the head round the ear, sometimes extending to the back and front of the same side. Has constant singing in the right ear. Has paralysis of the sixth nerve of the left side. Has a little pain in the left eye; cannot read test-type "12" with it; with the right eye can read test-type "3" with difficulty. Tongue deviates strongly to the right side; tactile power of tongue and of cheeks on each side the same. In the palm of the hand feels two points six lines apart on right side, four on left. Intelligence considerably impaired. Pulse 120, the same strength on both sides. Bowels so constipated as to be confined for a week together if no medicine be taken, the stools being very hard. Even with several strong doses of purgative medicine in succession, very often no action of the bowels is effected. The expulsive power of the bladder is "greatly impaired." He sometimes passes twenty-four hours without making water. The patient is generally very impatient and irritable.

After the treatment, consisting chiefly of ice to the spinal region, varied from time to time according to the require-

ments of the case, had continued until September 24th, the following was the condition of the patient:—

He can now raise his right arm vertically above his head; can extend his fore-arm vigorously, and all the fingers and the thumb completely. Can balance himself on the right leg without support. Can extend and flex the toes of the right foot very considerably, much more than formerly. The right leg decidedly warmer than before using the ice. In walking he can now put his left foot flat, there being no dragging of it as formerly. The pain of the right side of the head and the singing of the right ear, though not quite gone, are markedly lessened. The pain in the left eye is still felt at times, but is also much lessened. The paralysis of the sixth nerve of this eye continues about the same. Can now read test-type "1 $\frac{1}{3}$ " with the right eye, and "8 $\frac{1}{2}$ " with the left. Feels two points at five lines apart in each palm. Intelligence very greatly improved. The bowels are now easily acted on by a slight dose of aperient medicine, and are thus open at least every other day. The expulsive power of the bladder is much greater than before treatment; in fact, quite normal. Urine is now voided about three times in the twenty-four hours.

10.—*Case of Paralysis of the muscles of the tongue and throat.*

September 13, 1863, I was consulted by Mrs. —, who, about four years ago, lost the power of her right hand for a time, but recovered it. A year later she had an attack of paralysis of the right arm, lasting only for a few days. The face was drawn to the right side, and the speech became "thick." She has never walked so strongly since this attack as she did before it. She had a third attack about thirteen months ago, when, having gone to bed well, she rose in the morning, and went to call her daughter, but found herself unable to speak. The arm was not affected at all this time. Both legs are now very weak, the right one being much the worst.

The tongue is still paralyzed, but its sensibility is normal. She can now protrude it slightly, and move it from side to side, but cannot speak at all. Formerly the tongue was stiff, and could not be protruded.

During the last two months she has become able to swallow fluids with difficulty, only a teaspoonful at a time. Has all her food minced, being unable to chew it, because she cannot guide it in her mouth. Uvula straight. Pupils equal, and sight fairly good. Forehead, face, submaxillary region, decidedly cool; upper extremities habitually cold. Sleeps well; appetite good; bowels regular. Goes out daily to walk, but feels a great stiffness in the limbs, particularly in the right leg and arm. The patient writes on a slate—"My nerves are greatly shaken; the most trifling thing makes me laugh or cry without any cause. I cannot account for this attack in any way. I have tried blisters, strychnine, galvanism, and homœopathy, without any effect. I have no headache nor pain of any kind, but often feel as if a band were bound round my head and throat (more round the throat than the head); and going up or down a single step, I fancy I must fall, though I know it is only a nervous feeling." I requested her to apply ice, until it melts, along the upper half of the spine, twice a day.

September 20th.—The patient looks better; the hands have been always warm since the treatment began, becoming so in three minutes after the use of the ice. Her expression is improved; she looks healthier, stronger. Pulse 92; tongue clean, bowels regular. R Ammonii Bromidii gr. v, Potassi Iodidi gr. iiss, ter die.

27th.—Feels very well; arms, but not hands, warm; bowels regular. Face often flushes while the ice is on. Can eat better, and can say "Helen" and "No." To make the hands warm by putting them in hot water, by friction, and by warm gloves. To continue the medicine already prescribed, once daily, and to take of Ferri Carbonatis cum Saccharo gr. x, bis die.

October 3rd.—Much the same, but has a little more

power in the tongue. Can say "Nothing." Bowels regular. Pulse 104. Continue the ice and the pills, and keep a roll of cotton wool beneath the lower jaw.

11th.—Is generally better. Can say "Yes" and "Fire" and all the letters of the alphabet except "w" and "y." The wool beneath the jaw has much increased the temperature there. Is always warm, *except just after dinner*; she has not the ice on them. To continue the pills, to put the ice-bag next the skin, and to suck jujubes in order to exercise the tongue.

17th.—Can now say "Bacon, finger, apple, paper, Mary, box." Hands warm, feet also. Pulse 100. Bowels regular. Tongue deviates to the right. Swallowing improved: takes a wine-glassful of porter daily. R Potassi Iodidi gr. iij, bis die. Continue the ice and the jujubes, and make continual efforts to speak.

I never saw this patient again.

11.—*Case of Chronic Hemiplegia, with extreme constipation and coldness of the paralysed side.*

F. J. aged 27, consulted me November 6th, 1863. He had to be carried into my room. Became paralysed seven years previously. The elbow is immovably flexed, the fore-arm is pronated, the fingers and thumb are powerfully flexed into the palm of the hand. Can raise the right leg a little, but cannot flex it at all, the foot is drawn inwards, cannot move the toes in any way. The tongue can be only so far protruded as to get its tip over the teeth, can drink with great difficulty, and only very slowly, can bite, but cannot grind his food. Has wholly lost the power of speech. Breathes stertorously, and is often afflicted with an uncontrollable sardonic laugh.

Temperature of right hand 83° Fahr., of left 87°, of right leg 84°, of left 89°. Bowels habitually costive, open about twice a week, sometimes only once if aperient medicine is not taken; makes water with distressing frequency.

The patient came to me from Ireland, whether he returned after visiting me once. I ordered ice to be applied along the whole spine three times a day. Owing to his adverse circumstances the treatment was continued only a short time. May 18th, 1864, he wrote to me as follows:—"When three weeks had elapsed [after the date the treatment began] an obstinate constipation, from which I had suffered for years, seemed cured. The temperature of my paralysed hand rose considerably, and for the first time for six years I hobbled about with a walking cane, and continue to improve."

In answer to an enquiry concerning his condition, which I subsequently addressed to him, this patient wrote to me, May 7th, 1866, that "since the very imperfect trial of the ice treatment" immediately after he first consulted me, he had "failed in procuring ice except for a day or two," when, as he said, "we had frost here;" that, nevertheless, his improvement had continued; that he had begun to "mumble a few words;" that "under favourable circumstances the palsied side is as warm as the other;" that "the bowels act very regularly;" and that, in respect to the excessive micturation with which he was troubled, "there is a grand improvement; for the last few weeks that failing has all but vanished, though it was nearly nine years old."

I regret extremely that this patient could not continue the treatment I advised: it is evident that it was doing him great good; and, to the extent of the benefit derived from it, the case would have afforded a still more decisive illustration than it is already of the remedial efficacy of the method in question, as well as an answer to an eminent London physician who saw the patient with me, and who then said to me, "Well you don't expect anything can be done here, do you?"

---

BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—Dr. Stewart, Hon. Secretary, thankfully acknowledges the receipt of £5, the annual subscription for the current year of the Marquis of Londonderry to this branch of the above society, per James Brownlow, Esq., J.P.

## ON THE TREATMENT OF TRANSVERSE FRACTURE OF THE PATELLA.

By HENRY J. TYRRELL, F.R.C.S.I., M.R.I.A.,  
SURGEON TO JERVIS-STREET HOSPITAL, ETC.

DURING the last three years seven cases of fracture of the patella have been under my care in hospital; five of the patients were men, two women; and the ages of the male patients were 35, 39, 45, 46, and 50 years. One woman was 25 years, the other 60.

All the fractures were the result of falls, and the direction transverse and about the centre of the bone or a little below it. In two of the cases—one male, and the female aged 25—the injury was so severe as to require very active treatment, both locally and constitutionally, for a few days, to arrest the inflammation set up in the knee-joint, and to prevent me from bandaging the limb tightly for a fortnight. In no case did I do so before the seventh day from the receipt of the injury.

The two first cases were treated on the single inclined plane, and turned out very well, union having taken place by ligament, the separation of the fractured ends being not more than three lines. In the third case, that of a man *æt.* 45, I followed Dupuyhen's plan, as laid down in his work "On Injuries and Diseases of Bones," page 229, translated and edited by Mr. Le Gros Clark, and although I carried out his directions most fully and accurately, I not only failed to get bony union, but the separation of the fragments was greater than in any of the other cases. Indeed, I quite agree with Mr. Clark in thinking that the uniform success of Dupuyhen's practice in obtaining bony union is unusual.

The principal object of the present communication is to describe a very simple, and what is of more importance to the patient, a very convenient and comfortable mode of treatment, as, during the treatment, it is not necessary to keep the patient for any lengthened time on his back. It must be obvious, also, that in the old, when there is a disposition to congestion of the lungs and abdominal organs, any apparatus which allows them to sit up, turn from side to side, and be removed with ease from one room to another, is a desideratum.

In the three cases in which I adopted the plan I am about to describe it answered admirably, particularly in the woman aged 60, who was very delicate, and suffering from a severe attack of chronic bronchitis; although, in none of these cases did bony union take place, still the amount of separation did not exceed two lines.

The apparatus consists of a long and thick paste-board splint applied the entire length of the thigh, leg, and foot in the following manner:—

As soon as the swelling about the knee has disappeared, and it is deemed advisable to apply any retentive apparatus, the leg and thigh being slightly raised, and the upper fragment of the broken patella being brought into its place by gently pressing the muscles of the front of the thigh downwards, I apply a strip of adhesive plaster, two inches broad, and sufficiently long to extend from the groin to the instep, and, while it is passed over the patella, the fragments should be accurately adjusted; the leg being still kept elevated, I roll a bandage from the toes upwards, and as soon as the knee is reached, before applying a figure of 8 around it, a semilunar wedge-shaped horse-hair pad, three inches broad and three-quarter inch thick at the base, should be placed immediately above the patella over the plaster, and the hollow of the ham carefully filled with cotton wadding. Then a figure of 8 bandage being applied so as to press the pad well downwards, the roller is continued up to the groin. I prefer rolling the thigh bandage in the way described to the ordinary method, from above downwards, as I believe it is less likely to be disarranged, and the elevated position of the heel, the figure of 8 round the knee and the plaster prevents the quadriceps muscle from acting on the upper fragment. The bandages being adjusted, I now take a piece of the strongest paste-board, sufficiently long to extend from the great trochanter

to the heel and twelve inches beyond, and of sufficient breadth to enclose three-fourths of the circumference of the thigh, knee, leg, and instep; and having thoroughly softened it in hot water (a convenient vessel for holding sufficient water is a hip-bath), as soon as it becomes sufficiently cool it is accurately moulded to the thigh, leg, and foot, and, in order to preserve its shape, a bandage is applied from the toes to the groin, and the heel is placed on a pillow. Next day the bandage being removed, the edges of the splint are neatly rounded off with a shoemaker's knife, and it is lined with a layer of fine cotton-wadding. The splint is now permanently applied and tightened by a bandage wound neatly from the toes to the groin, or if the weather is warm a few straps, such as are used in bracing up the sides of a box splint, will be sufficient. Finally, the leg is slightly elevated by placing a pillow under the heel. No danger of acting on the patella need be apprehended (as the whole lower extremity is one fixed piece) by the patient turning on his side or sitting up. If the bandages and splint have been properly adjusted it will not be necessary to stir them for a considerable time; indeed, in one case I only took them off three times during eight weeks.

It will be observed that I place no pad beneath the patella for the following reasons:—

1st. It is not required; as the lower fragment being not acted on by any muscle, has no tendency to be displaced.

2nd. A pad so placed is almost certain to tilt the superior edge of the lower fragment upwards and forwards. No danger of interfering with the circulation of the circumflex-articular arteries can exist by the plan of treatment above described, as the bandage around the knee is not so tightly applied as to constrict them.

If it is thought desirable (as I believe it is) to keep the knee fixed for a certain time after the patient is allowed to walk about, I know of no better splint for the purpose than can be formed by simply cutting the paste-board of sufficient length to extend from the middle of the thigh to the ankle, and removing the foot-piece.

## MEDICAL SOCIETY

OF THE

## COLLEGE OF PHYSICIANS OF IRELAND.

THIS Society met on the 22nd instant to consider the late epidemic which Dr. Stokes has named "Malignant Purpuric Fever," but considered by others to be "Cerebro-Spinal Arachnitis."

The President, Professor STOKES, in the Chair.

He declared the order in which the various cases were to be brought forward, which had been determined by ballot; and called upon the Honorary Secretary, who then read the following communication by Surgeon-Major COGAN, 2nd Battalion, 2nd Regiment:—

The following are some brief notes of cases of a disease (supposed to be what is now called "Black Death") that came under my observation lately, but I cannot say if I am justified in giving it such a nomenclature, as, in all my experience of epidemics, I have never met with any disease presenting appearances or symptoms similar to what I shall now briefly state.

In order to arrive at some conclusion, as to the origin of the disease, and to its making its appearance in this barracks, I shall first commence by stating that part of the regiment was out on duty with the Thurles Flying Column, and when in Thurles, the beginning of April last, two men of the regiment were attacked with typhus fever; one of them died in twenty-seven hours, and it was reported to me by some of his comrades that he was covered all over with purple spots when he died. The other man was attacked at the same time, and has since recovered, but, as he has not yet returned to his regiment, I cannot say anything more about him.

The Flying Column about this time was broken up, and the detachment marched from Thurles to Roscrea, taking two days for the journey. On the day of their arrival at Roscrea (5th of April), one of the men complained of febrile symptoms, and the officer in command very judiciously ordered him into the regimental hospital at Birr, by train, a distance of about ten miles. I saw him immediately on his arrival, when symptoms of typhus fever soon presented themselves; he got through the attack steadily but slowly, and when convalescing he injudiciously exposed himself in the open air on a wet day, and got a relapse, from which he died eleven days afterwards.

After two days' halt at Roscrea the detachment came in by train to Birr to rejoin the head-quarters of the regiment. Nothing of any importance occurred among them until the night of the 13th April, six days after their arrival, when a little boy, 10 years of age, was suddenly attacked with strong fever and involuntary diarrhoea. I was not called to see him until nine o'clock next morning, when I found him with a hot burning skin; bowels continually moved without any previous notice; great prostration; thirst; a dark brown furred tongue; pulse small and quick, and his extremities covered all over with dark purple spots. At two o'clock P.M. I partly succeeded in arresting the diarrhoea, bilious vomiting then set in, which was copious, and continued until five o'clock P.M., when it ceased, he then became quite unconscious and comatose; and at seven o'clock P.M. same date, he died—the purple spots increasing in size and colour all the time. Duration of disease seventeen hours.

The treatment in the early stage consisted of Dover's and Grey powder, in small doses, together with stimulants. In the latter stage vomiting set in so violently that nothing could be given to him. I may here mention that this child's mother washed for some of the men who were out with the flying column; and the room where she resided was well ventilated and not overcrowded.

*Case 2.*—On the morning following the day on which the case above alluded to occurred, there were two fresh attacks, one a young married woman, whose husband had been out with the flying column, living in a small room by themselves, which was well ventilated and not overcrowded. The other a recruit of ten months' service.

The woman, when I first saw her, two hours from first attack, complained of a very severe pain in her head and back, and all over her body. Great thirst; tongue moist, and covered with a creamy substance. She speaks at times somewhat incoherently, and the body is covered all over with large dark purple spots; her husband states that the eruption made its appearance at the same time with the fever. After the administration of a strong mustard emetic she threw up nearly a gallon of bilious fluid which relieved the headache, and after a few doses of the diaphoretic mixture were given, a copious perspiration was established, which relieved her of the bodily pains. She progressed favourably, only requiring a mild purgative occasionally. On the third day severe pain in the forehead, left eye, and temple set in, accompanied with conjunctivitis and chemosis of left eye; two days later, after great suffering (which leeches and a blister did not appear to palliate), pus formed between the layers of the cornea, and vision has since been obscured. The purple spots, which were chiefly on the extremities, remained for three days before they faded away.

She is now convalescent, with the exception of the eye, and I am in hopes that she may yet partly recover her sight.

*Case 3.*—Pt. C., æt. 19, a recruit of ten months' service, of a delicate constitution, had not been out with the flying column, but slept in the same room with some of the men who had just returned from it, and whose washing was done by the mother of the dead child already alluded to, reported himself sick at nine o'clock A.M. On the morning of the 14th of April, while waiting to be called into the

surgery, he fainted; he was carried into a ward and placed in bed, and as soon as he recovered a mustard emetic was given to him which brought away large quantities of bilious fluid. In less than an hour after admission he became quite delirious, and his lips and teeth were covered with dark sordes. It was not until a blister to nape of neck took effect that consciousness returned, and then he complained of pain in head, and all over his body; tongue very dry and brown, and the papillæ elevated; he also complained of intense thirst; there were some slight patches of purple spots, but not so visible as in the two former cases. The bowels were obstinately constipated, and two doses of haust. cathart. were given to him at intervals without having the desired effect. A large turpentine and oil enema was administered, which did not take effect for nearly three hours, when he nearly filled the night stool with a quantity of small black fetid lumps resembling pills, which gave him almost instant relief, and he then passed a pretty good night. In the morning following he answered questions rationally enough for a short time, when his mind would wander again. The skin was now moist, but the dry sordes on tongue and lips continued; he complained of great thirst.

The above symptoms continued much in the same way for the next forty-eight hours, when he began to improve in every respect, with the exception of the thirst, which was still very great. He continued to improve steadily for the next seven days, until he imprudently exposed himself to a draught at the window, which brought on a slight relapse, but he is now almost convalescent.

In this case it will be observed how quickly the head symptoms made their appearance, and the obstinate constipation he suffered from; and, although he was not out with the flying column, his case, along with the others, go to prove that the contagion was imported by the men from Thurles, where typhus first made its appearance.

The next case was more interesting, and of greater importance, and presented other and different symptoms to those already described.

*Case 4.*—The patient was a lively, interesting girl of four years of age. About 3:30 o'clock P.M., on the 25th of April, she was suddenly attacked with violent headache, pain all over her body, particularly in the abdomen, a burning hot skin, a full and so quick a pulse that I could hardly count it. The parents gave her a warm bath, and at nine o'clock P.M., when they observed the child getting worse, they sent for me. I found the child suffering from the above symptoms, and very restless, a desire to vomit, but could not throw up anything, and the skin was covered all over with a purple eruption. A mustard emetic relieved her very much, as she vomited a large quantity of green bilious fluid, after which she slept, and passed a pretty good night. At nine o'clock A.M. I was informed that she was in a fit, and when I arrived she was just recovering from it, but I observed great muscular twitchings all over her body, particularly in her arms, legs, and those of her face. The arms were in a constant state of jerking, and her legs drawn up. These symptoms increased, and she was constantly raising her body up by her heels. She now required some person to be always in attendance on her to prevent her falling out of the bed; her face presented a wild appearance; the eyes staring, and the pupils much dilated; she did not speak, but constantly giving loud and short screams, and putting her hand to her head, indicating pain there; the bowels were opened but twice during her illness, and the discharge was very fetid, accompanied with wind.

All the symptoms increased in severity, particularly the screaming. Muscular twitchings and restlessness, and the purple spots became larger and darker, and at 8:30 o'clock P.M. she died. Duration of disease seventy-seven hours.

The treatment adopted in this case was a mustard emetic at the commencement, followed by a diaphoretic mixture and purgatives; mustard poultices to forehead, back of neck, and spine; cold applications to the head; latterly, turpentine and oil enemata, ammoniated tinct.

valerian; small and repeated quantities of wine, brandy and lemonade, for drink. All these remedies appeared to give relief, but it was only temporary, as the symptoms returned in a short time as bad as ever. The turpentine enema appeared to give the greatest relief. The valerian was not given until within eight hours of death, and the first dose produced perfect quietness for five minutes, but after that nothing appeared to give her relief.

*Case 5.*—The next and last case was a delicate little boy of eight years old. He took ill on the night of the 29th April, when he vomited and was purged; but in the morning he got up, ate his breakfast, and went to school, where he had only been one hour when he was sent home ill. It was not reported to me until five o'clock p.m. that day. I found him complaining of great headache, and pains all over his body, a dry brown tongue, very hot skin, and he was covered with purple spots, countenance anxious, and the pulse full and quick. He became speechless at nine o'clock p.m., and was in spasms and convulsions all the night, and he was continually screaming. Towards morning he became better, the convulsive fits coming on only every second hour, but the twitching of the muscles were continuous, and there was muttering delirium. He remained so until the afternoon of next day, 2nd May, when the convulsive fits set in worse than ever, which continued so until 4:30 a.m. next day (the 3rd), when he died apparently in great suffering.

The twitchings of the muscles of his face and arms were very visible, and he was constantly jerking his arms and legs; and the purple spots became larger and darker in colour. Duration of disease, from my first visit, fifty-nine hours, but from first attack fourteen hours more.

The treatment consisted of a mustard emetic, diaphoretics, turpentine and oil enemas, mustard poultices to forehead, back of neck, and spine, wine, lemonade, &c., &c.

The foregoing five cases occurred within the past month in these barracks during the prevalence of an outbreak of typhus and continued fever among the troops; and, I think, it is clearly proved that it was not from defective ventilation, overcrowding, nor bad drainage, the disease made its appearance here, but entirely depending on the importation of it from Thurles by the men who had been there.

The first case (that of the child whose father had not been with the flying column, but his mother washed for the men who had been out) made its appearance during the time the first washing was being done after their return. The next was the young married woman, whose husband had been out, and afterwards they slept together; and the recruit, who slept in the same room with the other men who had been out. The origin of the disease in the two children last-mentioned can be similarly traced.

It is not my intention to make any comments on the nature of this new, but strange, disease. I shall leave it to those who have already seen something of it, and who have had greater experience.

The striking features of the disease are the febrile symptoms, and the purple eruption making their appearance almost at the same time, and the delirium setting in so soon afterwards.

Dr. GORDON read the following:—

On looking back upon the numerous cases of such illness which may be said to compose the present epidemic, the first circumstance calling for remark appears to me to be the preponderance in different cases of various sets of symptoms, in some almost entirely (at least on superficial examination) referrible to the nervous system, and in others, with at least equal partiality, confining themselves to the more obvious tokens of blood contamination.

To this fact we evidently owe the different nomenclature of the disease, cases of the first kind being termed cerebro-spinal meningitis, and of the latter, spotted fever or some other more formidable name.

It appears to me, therefore, to be desirable in the first

place to decide, whether we are warranted in classing under the one name the various cases which have been met with, presenting either of those sets of symptoms, or whether we are to consider them as separate and distinct diseases. I will briefly relate two cases which have occurred to me since the publication of my remarks on this disease, in the *Dublin Quarterly Journal* of the 1st inst.

A lady, 37 years of age, was complaining for about a week of lassitude, occasional diarrhoea, want of appetite, nausea, and inability to manage her household affairs as usual. If she walked out she became giddy, and her head so confused that she had to return home immediately. Driving shook her so that she could not use this mode of exercise either. However, on Sunday, the 12th, she was induced to take rather a long drive to accompany her husband, who had been also unwell. The entire time she was out she was occupied shifting her position so as to get some rest for her back. When she came home she had to lie down, and applied all sorts of domestic remedies, soothing and counter-irritant, but without relief. At eleven o'clock I found her suffering great pain in her back, shooting forwards towards the epigastrium. This pain was most intense. She had also pain shooting upwards towards her head, in which she complained of great weight, and downwards towards her legs, which she said were powerless; she had also a peculiar sense of constriction around the lower part of her chest, which grew. She was in a state of partial collapse, and the intensity of the pain seemed to be the only thing which prevented this from being complete.

She soon vomited—the vomiting was first the remains of food, which she had rapidly swallowed on her return from driving, under the idea that her distress arose from fatigue and hunger. It soon became watery and green, and was provoked by the least motion. This intense pain and vomiting continued for fully six hours. She got no sleep until seven o'clock in the morning, and then, on waking, she had cramps, pains down the legs, great sensibility of the surface of the body to alterations of temperature. This was obviously a case of spinal arachnitis, but there were also some few symptoms which, in my opinion, warrant our recognising it as a secondary affection. The condition of the pulse was some element in the diagnosis. It never assimilated the pulse of cerebral or spinal inflammation; it never rose above 84, and this is, as far as I have been able to judge, a great peculiarity of this epidemic, as contrasted with typhus or typhoid fever—the comparative slowness of the pulse. We had here also a weakly acting heart, and immense sense of weakness, long after all collapse had passed away, and as the disease yielded to treatment, we had further confirmation as to the blood origin of the disease. The pain in the back and vomiting yielded at length to the extensive use of an exhorative of a. a. L. C. C. and T. B., which produced most powerful counter-irritation, and, of course, allowed of the pre-absorption of the B. Since the irritability of the stomach has been allayed, wine and quinine are completing the cure. There were never any spots in this case. The following is a remarkable contrast to the above case:—

A young gentleman about 23 years of age having bathed when somewhat fatigued, was attacked with the usual symptoms of anorexia, and shortly afterwards his face and the upper part of his body was covered with an eruption somewhat like measles, but the patches were irregular in size and shape, they were dark coloured, they were rough looking on the surface, they could be more or less completely effaced by strong pressure, they were thickly interspersed with petechiæ, they spread gradually over the whole trunk, being most thick on the back, passed down the thighs, and have come out sparingly about the knees, and on the dorsum of the feet.

In this case the eruption forms the grand prominent feature (it is totally unlike measles, and may at once be excluded from the ordinary exanthemata by the mode of its development, and by its duration. It is still coming out on the lower parts, and has not yet disappeared from the upper part), the other symptoms of blood

contaminated are, as in the lady's case, a weak condition of the heart, a feeble but not a rapid pulse, 80 is about the average, but we have the following symptoms of a secondary affection of the cerebro-spinal meninges, corrugation of the brow, occasional pain in cervical region, sense of weight in head, occasional subsultus, nausea, and sometimes diarrhoea, with a furred and that peculiar symptom—a greenish tongue.

I bring forward these brief notes of these two cases, merely as examples of what I stated above the marked predominance of one set of symptoms in certain cases. The grounds then which, in my opinion, exist for our classing these two sets of cases under the one nomenclature are first, that in many well-marked cases we find the two sets of symptoms, if I may so speak, combined evidences of profound blood-poisoning, and proof of extensive cerebro-spinal meningitis; 2ndly, that although the indications of blood-poisoning may greatly prevail in one case, and the symptoms of lesion of the nervous centres in another, they never do so to the complete exclusion of the less obvious phenomena; and 3rdly, that *mutatis mutandi*, the same plan of treatment will cure the affection whichever train of symptoms predominate, due care being had to the probable secondary affections which the nervous centres may have to undergo.

What the general title should be, is another question altogether.

Wood—who, in the last edition of his "Practice of Medicine," gives a very satisfactory account of the disease—wishes it to be called *petechial fever*, as no other form is so peculiarly marked with true petechie, and as there is no other phenomenon more constantly present which can serve as a basis for nomenclature.

All physicians who have had opportunities of seeing epidemic fevers on a large scale, have met with typhus fevers without eruption, and typhoid fevers without eruption, and therefore the fact that cases have occurred of this epidemic without eruption can form no well-grounded objection to the title being adopted; but adopting another basis for our classification, we might perhaps, with more advantage, term it cerebro-spinal fever, as we call others, from the habitat of their quaint phenomena, gastric, isenteric, &c.

Dr. LYONS read the following:—

*Case 1.*—This case may be briefly noted. It is that of a youth in the prime of vigour, aged 19, fully developed; an energetic cultivator of athletic sports, and apparently in perfect health prior to the seizure which struck him down with such a terrible fatality. The details of this case I owe to the kindness of Drs. Clifford and Grant.

An officer, of one year's service, 19 years of age, full habit of body; sanguine temperament, and hereditary predisposition to head affection, reported himself sick, on Tuesday morning, April 16th, to Dr. Grant, stating that he felt bilious and out of order, and enquired whether he could go to the Regimental races (Baldoyle). As his tongue denoted slight disturbance of the stomach and liver, he was ordered a mild mercurial purgative, to be followed by a saline draught, and enjoined rest. Visited again at noon—found better and anxious for food. Ordered very light diet. Seen again at six P.M. The bowels had been freely moved; copious biliary evacuations; otherwise not much change. At eleven P.M. finding that there were feverish symptoms and headache, ice was ordered to head, and a saline diaphoretic. Dr. Clifford was then sent for, and on seeing him soon after, he found the headache continued, and that irritability of the stomach had set in, the matter vomited being dark purple, coloured with a slight amount of rosy mucus. Ice allayed irritation of the stomach, and he fell into a tranquil slumber for sometime; pulse soft, not frequent; skin moist and perspiring; on waking he was perfectly sensible, and did not complain much of headache; the rest was tolerable during the remainder of the night, and in the morning there was a marked improvement in all the symptoms; complained only of headache (frontal). At nine A.M., he was removed to a fresh bed,

and left proceeding in a most favourable manner under charge of Dr. Grant. He continued tranquil for about half-an-hour, when he suddenly became restless, and was with difficulty restrained in bed. At eleven A.M. symptoms of congestion of the brain set in; small dark spots became now visible which had not existed before; the head symptoms increased rapidly and resisted all treatment (external). Internal treatment being impossible, as he could not swallow.

The treatment consisted in unloading the intestines and promoting secretion from the liver, watching carefully for head symptoms, applying ice, &c., &c., and when the congestion of the brain occurred, leeches to the temples, turpentine enemata, mustard sinapisms externally used and renewed over the spinal column, epigastrium, limbs, &c. Towards the end the action of the heart and strength of the pulse became gradually weaker; the respiration more impeded, and he quietly sank at about one P.M., having been insensible since eleven A.M. There was no retraction of the head.

There was no post-mortem examination made.

The body was seen at about 1.45, by Dr. Stokes and Dr. Lyons. The head and face, as well as the neck, were of a dark cyanotic tint. The surface of the body generally was not abnormally discoloured, but on the back there was a considerable amount of deep congestion of the skin between the shoulders, and down to about the waist.

Here and there upon the back, flanks, abdomen, calves of the legs, and inner parts of the thighs, were to be noted some dark, bluish-black spots, perhaps a dozen in all, some angular, more irregularly rounded, from two to three lines in diameter, unaffected by pressure, not prominent above the skin, and feeling firm to the touch.

*Case 2.*—For an opportunity of seeing the next case, I am indebted to Dr. Banon, who wished me to visit the patient with him, as he had not previously met with a case of this singular and appalling malady; it is but just to add that he had already made an accurate diagnosis and prognosis of the nature and formidable character of the disease under which our unfortunate patient was found to be labouring.

When seen by Dr. Banon and myself, at about 11.30 P.M., on the 24th April, she was found lying on a sofa perfectly unconscious, and wholly incapable of being roused, but she lay with her knees drawn up, showing that muscular power was not altogether annihilated; her breathing was very quick, about 40, short, and somewhat noisy; the pulse was all but imperceptible, and the heart's sounds were with difficulty heard by the stethoscope. The eyes were lurid; the pupils, of about medium size, were found to be wholly insensible to light. A clammy sweat covered the body; the feet and hands were cool, but had not quite lost all animal heat. The most notable feature about the case was beyond all question the presence of numerous dark purple spots, thickly strewn on the face, trunk, and extremities. They varied in size from that of a sixpence to that of a half-crown piece, and upwards, and here and there seemed to run into each other, while in various parts of the body the intermediate skin wore a general dark cyanotic hue.

The most active treatment, by external and internal stimulation, medicinally and otherwise, proved unavailing, and the patient died at about one o'clock A.M., on the 25th.

Little of an accurate character could be ascertained as to the history of this case. The patient was about 40 years of age; unmarried; a seamstress; she had pursued her avocations to the day of her fatal illness, and it was late at night when medical aid was first sought. This, in itself, is sufficient to show the insidiousness of the earlier symptoms, which were such as to raise little or no alarm, while, towards the close, the suddenness with which the eruption of purpuric patches was thrown to the surface, and the rapid supervention of symptoms of failure and depression of the vital powers, with the speedily fatal issue, mark, in a striking manner, one of the most characteristic features of this strange and terrible malady.

It may be worth while to note that the patient's mother, not unfamiliar, as we may presume, with sickness in many a form, repeatedly exclaimed, "Oh, this is the new disease. I'm sure 'tis the new disease," &c. Death took place in about thirty-six hours from the time at which any notable departure from health was observed.

*Case 3.*—I had the advantage of seeing this case in consultation with my friend Dr. Byrne. The patient was a fine, handsome boy, of about 11 years of age, of well-nourished frame. On the 24th April he took a long walk with a grown relation; towards evening he sickened and complained of headache, when some aperient medicine was administered by his friends. Later in the same night he was visited by Dr. Byrne, but until about twelve that night no spots of any kind were visible on his person. On the 25th he was seen by me in consultation with Dr. Byrne, who had at once, on seeing the spots, recognised the true nature and formidable character of the disease; although, to the ordinary observer, there was little about the patient to show the danger in which he was.

When seen at one P.M. on the 25th, his state was as follows:—He was sitting up in bed; made little or no complaint of headache, which he said was better; of sickness of stomach, for there was none; or of any other specific ailment of what kind soever; he was perfectly clear and collected; had a full, strong voice; could rise in bed, turn, help himself in every way, and wanted to be allowed to sit up; his chief inquiry was, "doctor, doctor, what are these spots?" pointing to numerous dark, blue, black spots on his arms and elsewhere. With such full possession of consciousness, and such an amount of muscular power as he retained, it was not a little surprising to find that there was a total absence of pulse, which was completely extinguished in both radials, and the heart's sounds were but faintly audible to the stethoscope.

The eyes were slightly injected, but the pupils were perfectly natural; the face was greatly discoloured, or rather somewhat dirty looking, with two or three angular spots on the left cheek, of blue-black colour, firm to the touch, unaffected by pressure, perceptible as lying in, above, and beneath the skin, and very much of the character of what are known as weals. These spots were found on the face, arms, forearms, backs of hands, on the trunk, and a few on the thighs and legs, which were generally somewhat of a cyanotic hue.

A mustard emetic was administered and freely taken, long retained, and at length but partially returned with no free effort at vomit, notwithstanding the aid of hot water. External and internal stimulation was freely employed, and all medicines and nourishment were readily taken and retained, but with no sensible improvement to his state. He was repeatedly seen both by Dr. Byrne and myself during the day, and all our directions were carried out with unflinching zeal. At about half-past six o'clock slight returning pulsation in the radial arteries could be faintly felt, but this proved only a fallacious symptom, and with little or no further change he sank at about half-past nine P.M., a little over twenty-four hours from the time when he first sickened, and less than twenty-two from the time the spots first appeared.

Of the three cases just cited it is to be observed, that as well as those previously recorded by me, all occurred in persons apparently in full vigour of health, with well developed and well nourished frames, of full habit, and in whom the adipose tissues abounded.

They are new to me in the character of the cutaneous spots and patches which they present. They all showed an absence of specific lesion of the nervous system. So far as I read aright their pathological indications, and long prior to their occurrence during their prevalence, and since I have had under careful observation, and treated numerous instances of the best marked specific lesions of the central portions of the nervous system and their membranes which this city has afforded.

Finally, I regard the pathological affinities of this strange malady to be rather in the category of those diseased

states which include blood-poisoning, yellow fever, cholera, the effects of sun-stroke, than with those in which active hyperemia in one stage, and lympho or purulent exudation in another stage, is poured on the brain, cord, or their membranes. But I am quite free to admit that their are two distinct but occasionally mixed types of disease in the late epidemic. I regard the disease which I have described as the algid condition of a zymotic malady, and I propose to designate it FEBRIS NIGRA. I shall be prepared to discuss its pathology more fully when the proper time comes; I now give place to the able contributions which are to follow.

Dr. JOHN HUGHES read the following:—

Jane Traynor, aged 6 years, was admitted into the Mater Misericordiae Hospital April 10th, 1867.

She went to bed on the night of the 6th in her usual health, and awoke next morning complaining of sickness of stomach. Afterwards she vomited, and both the nausea and vomiting continued up to midnight. Her mother also states that the surface of her body was then quite livid.

On the morning of the 8th dark spots were to be seen on her face, legs, and arms, and in the evening on the body also.

Dr. Montgomery, of Blessington-street, saw her on that day, and his description of her condition corroborates that of the mother. He also says that she was semi-collapsed, almost pulseless, and rather cold. On the night of that day her head was first remarked to be drawn backwards. The spine appeared curved and the legs bent.

On the 9th, there were no new symptoms, but those already existing were more strongly marked.

On the 10th, the day of admission, the above symptoms were very prominent—the retraction of the head, the arching of the spine, the flexed position of the limbs, the rigidity of the muscles, the extreme sensibility of the surface, and the pained and anxious expression of the face; the knitted brow, the suffused eye—were very remarkable, and plainly indicated cerebro-spinal disturbance.

Superadded to these symptoms, there was a peculiar eruption of dark-coloured livid, almost black, spots, over the entire body, except the neck and scalp. The eruption was, however, much more abundant on the face and extremities than over the trunk; and the size of the spots was also larger in the former than over the body, in some instances attaining the size of a sixpence.

Those spots were irregular in shape, but the smaller ones were circular, or slightly oval. In fact, looking at the child as she lay in bed, a superficial observer might not unnaturally conclude she was labouring under an attack of measles of an asthenic or malignant type.

It is hardly necessary to add that the pulse was extremely rapid, and occasionally imperceptible.

The heart sounds were natural; the body was wasted; the temperature low; sensibility of surface exalted; the eyes suffused; pupils natural, with little expression, and apparently diminished consciousness; bowels free, evacuations passed in the bed; great restlessness; incessant whining, and jactitation of the arms.

11th.—Pulse still incalculable, and occasionally imperceptible. Rested pretty well last night. No convulsions, nor any other appreciable change.

12th.—Pulse 138; she is not so dull; occasionally notices what is going on about her; she lies in bed quietly, but whining almost continually. The conjunctiva of left eye is more inflamed, and the eye looks dull; vision, however, is not impaired. Some portions of the rash are of a redder colour; a few, however, have become almost black, especially one, situated over the left elbow, of an oval shape, and surrounded by a red margin, which is nearly the size of a shilling.

13th.—Pulse 140; very weak; rested badly last night; continually screaming as if suffering intense pain; rash generally becoming of a reddish brown colour.

The cuticle over those spots which were noticed to be the darkest (almost black) is now raised by effusion of a sero-sanguineous fluid underneath it. The retraction of

the head and the arching of the spine are still strongly marked, fully as well as heretofore, although she appears somewhat more conscious, and calls occasionally for her mother, and recognizes the sister on duty in the ward.

14th.—Pulse 134, and fuller; on yesterday a vesicular eruption appeared on the shoulder, on the chin, and on the bridge of the nose. The former rash has assumed a brighter colour. She takes broth and milk freely; other symptoms unchanged.

16th.—Pulse 120, stronger; slept a good deal last night, and also to-day. The measly rash is fading, but the vesicular portion of it, which had previously ruptured, is replaced by a yellowish superficial ulceration surrounded by an inflamed margin. The eye is still inflamed, but does not look so dull. The upper extremities have completely lost their rigidity, and the head is less retracted; takes nourishment freely.

18th.—Pulse 100; rested well last night; is livelier and more sensible to-day. The head is still retracted, and the spine arched, but there is no rigidity of the muscles, and she allows herself to be placed in a straight position; the rash is fading everywhere, and there is now none visible on the body; the eye is clearing.

From this date forward her convalescence was uninterrupted though slow, and we remarked when every other symptom of her severe illness had disappeared, there was strabismus apparently of the left eye. Thinking that this affection might have existed previous to her present illness, we made particular inquiries of her mother, who assured us she never had anything wrong with her eyes, and in confirmation of that statement she is now fast recovering from that symptom.

The treatment I adopted in this case was free, and I may say very decided—counter-irritation over the scalp, with internal administration of codide of potassium and bark, at the same time supporting the system with wine and nutritious diet.

I looked upon this case as one of cerebro-spinal meningitis, to which was superadded this peculiar eruption. For all the most prominent symptoms pointed to such a lesion, and I was the more strengthened in this opinion from having had in the same ward two other cases shortly before, which presented almost all the same symptoms *without any eruption*, and ended fatally. One was a girl named Charlotte Smith, aged 11, who was admitted on the 1st, and died on the 11th of March. This patient had the retraction of the head, and arching of the spine with flexure, and rigidity of the limbs, suffusion of the eyes, convulsive fits, and other symptoms, referrible to the cerebro-spinal system, well-marked on her admission, and for a week before; and this condition of the spine; and muscular system was so permanent that the body could not be straightened, even after death.

On making a post-mortem examination the only lesion found was an effusion of serum into every cavity of the brain, and into the spinal canal without any trace of lymph or pus.

Another was Mary Hart, aged 7 years, was admitted from the dispensary on the 27th March, and died on the 8th of April.

She had been ill for a few days, but on admission had no special symptoms, except great dulness, listlessness, and depression of the vital powers, and loss of appetite.

On the third day the head became retracted, the spine arched, the limbs flexed and rigid, and she was seized with convulsions. Some days before her death she lost her speech and sight.

In this case no post-mortem examination was allowed; however, there can be little doubt we should have found pretty much the same appearances as in the case of Charlotte Smith who died some days before her admission, having had almost exactly the same symptoms.

(To be continued.)

## Review.

THE POISONS OF THE SPREADING DISEASES.  
BY BENJAMIN W. RICHARDSON, M.D., &c. London: J. Churchill and Sons.

THIS pamphlet consists of a lecture delivered before the congress on the sewage question at Leamington, last October. Anything coming from the pen of Dr. Richardson is sure to excite considerable attention, and when, as in the present instance, he ventures positive statements that are to a large extent new, and the result of his own enquiries, we cannot better serve our readers than by furnishing them with a summary of his views. First of all then we are assured in this lecture that each of the spreading diseases depends on its own specific poison. Of all these the great type is snake-poison. Like that, each of the others may be separated, dried, again mixed with water, evaporated, &c. In the case of small-pox the poison is separated in almost a pure state by nature. In a dry state it is innocuous, but the moment it is moistened it resumes all its activity. In the same way all the poisons of this class dry solid, in which condition they are inert. All of them can be charged with water, and are then active, but they can be diluted to such a degree as thereby to lose their poisonous properties. The poisons are also transferable in vapour, and it is to a large extent through this, that a healthy person becomes attacked by being brought into the room of a person sick of these diseases. On the other hand, after death there is no longer vaporisation, but rather the reverse process of condensation, and Dr. Richardson, after special investigation, is convinced that the corpse of a patient who has died of one of these diseases is no longer infectious. There must be heat enough to carry the vapour.

Yet the heat must not be too great, for the poison of typhus is destroyed at 100° Fahr., and none of them can exist at a heat of 212° Fahr.

Besides dilution and heat these poisons are destroyed by oxidation. Their exposure to moist oxygen rapidly renders them inert. Ozonised or electric oxygen is still more rapid in its action. Chlorine is instantaneously destructive. Iodine and bromine are nearly as effectual as are also sulphurous and nitrous acids. Last of all, sunlight is very powerful. By experiment it has been shown that snake-poison is destroyed by sun-light, and that apart from the temperature.

To these facts we have to add that the poisons may be preserved artificially. Of the agents that preserve them cold is the most powerful. Besides this sulphur, creasote, arsenic, and perhaps other substances, will keep the organic poisons for an indefinite period. Lastly, these poisons cannot survive the process of decomposition. Thus, dissection wounds from recent bodies, are very serious, but a few days after death the poison is believed to have been destroyed.

As to the origin of these poisons Dr. Richardson traces them all to albumen, and holds that the changes in that body may be developed afresh in the human body. Should this be clearly established one could scarcely hope ever to banish all these diseases from the world.

The modes of communication of these poisons are all deducible from the properties already described, and as our space is limited we will pass over this, and briefly refer to the modes of destroying them—the methods of disinfection.

The best, easiest, and most natural is active ventilation. With this should be combined sun-light, which, like heat, destroys the poison. Dr. Richardson thinks that in a hospital for typhus, there could be no contagion if the patients were kept at a temperature of 100 Fahr. In a room of a temperature of 70, one dram of pulverised iodine, placed in a box and covered with a piece of muslin, will volatilise in the course of 24 hours, and destroy the poison there may be in the atmosphere. With a spirit lamp the metalloid may be rapidly diffused, but where this is not at hand placed in a saucer, and that put in hot water, the same effect would be produced. Iodine is much safer than chlorine, which, when he employs, Dr. Richardson furnishes in two-dram bottles, which can be opened, one at a time, at a distance from the patient.

Dr. Richardson also believes iodine to be the most effectual disinfectant to employ when the poisons are passing from the patient in a fluid state. For example, he would use it to disinfect the discharges of cholera and typhoid.

It is generally inconvenient to put the linen of patients into water at 212°. In this case they are better put into cold water first, as under 50° they are inert, then let them be put in a

room at 300°, with a good draft. If this cannot be done, let them be thrown into a cauldron of boiling water, not taken off the fire. With such precautions as these Dr. Richardson has never seen these diseases spread, and he says the poisons are harmless enough "if you know how to manage them." They may be isolated and kept for years. "You can put them in your pocket and carry them about, if you know how to treat them."

Lastly as to the utilization of sewage. This is believed by the author to be a point of very secondary importance to that of public health, which forms the side of the question to which this lecture is chiefly devoted. We have thus summarised the views of an able observer, and we refer all interested in the subject to the pamphlet under notice.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 29, 1867.

THE RECENT EPIDEMIC IN DUBLIN.

WE need scarcely inform our readers that within the last twelve months, a number of cases of a strange and peculiar character have occurred in hospital and private practice in the city of Dublin. The readers of our columns have not only been made aware of this fact, but have had set before them details and records of more than passing interest, and of grave importance.

These cases have been sufficiently numerous to be classed in a collected form as an Epidemic, and as one at this time peculiar to Ireland, and specially to its Metropolis, in which most of the recorded instances seem to have occurred.

On a recent occasion the Medical Society of the Irish College of Physicians discussed the subject of Cholera with an amount of dignity and ability which has been rarely equalled; and to THE MEDICAL PRESS AND CIRCULAR was confided the important trust of publishing the numerous papers then read, and the brilliant and scientific discussion which followed them. The importance of facts and opinions so collected can scarcely be over-rated; and such, we have the best reasons for knowing, is the unanimous judgment of the Profession.

With regard to the recent or present Epidemic in

Dublin, a similar course is being pursued; and we are thus able to-day to lay before the Profession facts which afford a most valuable addition to the literature of medicine. On Wednesday last, at a very crowded meeting of this Society, several papers were read; they were concluded at an adjourned meeting on Friday last, and were on that evening followed by a practical and lengthened discussion. All the papers and a full report of the discussion will appear in due course in our columns; and we therefore forbear expressing any opinion on the disease itself, or on the proceedings of the Medical Society regarding it.

So long ago as the 1st of April, 1846, Dr. DARBY, of Bray, gave early information about cerebro-spinal arachnitis, in THE MEDICAL PRESS, and he was followed by the late Dr. Mayne, in the *Dublin Quarterly Journal* for August, in the same year. In THE MEDICAL PRESS AND CIRCULAR for 16th May, 1866, Dr. LYONS, of Dublin, seems to have first published matter belonging to, or, at least, connected with the recent epidemic. In the following number, (23rd May), the same gentleman recorded a case of decided cerebro-spinal arachnitis. Again, in the very next number, (30th May), we published an undoubted case of the recent epidemic, which just then had occurred in the practice of Professor BANKS, and we called attention to that case, and to the phrase, "Black Death," in connection with it, in a leading article. Further, on the 13th June, 1866, we published a case by Dr. LITTLE, on the 3rd April, 1867, another by Dr. RIDLEY; and on the 24th of April a third, by Dr. BENSON, jun. On the 1st of May, we gave the last published in this journal, that by Dr. BELCHER, and we refer to it particularly, because it records references to the literature of the subject, which have not been given in connection with any of the previously published reports, which it to some extent summarizes.

The epidemic in question has been variously designated in our columns under the names of cerebro-spinal arachnitis, cerebro-spinal meningitis, febris nigra, and black death. The last of these names appears to us to be, if not a mere sensation title, at least specially calculated to mislead ordinary medical men, for the simple reason that the terrific title, "Black Death," is the legitimate literary designation of the universally known mediæval epidemic so clearly described by HECKER.

THE PURGATORY OF PERIPATETICS.

WHILE many columns of the daily papers are being filled with descriptions of the wonders collected in the Great Paris Exhibition, and thousands of families are discussing their plans for visiting that International Show, it cannot be out of place for a medical journal to allude to the one inconvenience of crossing the Channel, which is present to the minds of a vast majority of the intending travellers, and, to not a few, may prove the only reason for staying at

home. Sea-sickness is an evil which few can afford to laugh at, and though usually it is but a temporary malady, subsiding almost as soon as *terra firma* is reached, yet, there are instances in which it undoubtedly originates or aggravates serious diseases. The strongest will, the iron constitution, the most highly-trained athletic system, are soon reduced to the helplessness of infancy by a toss on the briny billow. Careful preparatory diet and regimen, and the whole array of drugs, afford no protection, or have proved of such little avail, that they have all been discarded, and, for the most part, men have made up their minds that the only thing is to endure with such fortitude as they can the evil that seems the inevitable accompaniment of even a brief sea-voyage. The impotency of remedies to alleviate the suffering caused by so apparently simple a disease has pointed many a jest about the uselessness of the medical art, and too often furnished the crowning argument of that prevailing scepticism in drugs which is ever repeating the advice, "throw physic to the dogs." Even that section of the Profession which is constantly in contact with sea-sickness seems to have fallen into the same acquiescence in the powers of Neptune, and ceased to study the phenomena of the disease, in the hope of bringing them into subjection.

Among the thousand-and-one remedies that have been proposed, there is, however, one which, in a scientific point of view, towers above them all, and on which the Profession, as a body, is imperatively called to pronounce an opinion, and because nearly every one in large practice must have an opportunity of putting it to the test. With such patients as are about to visit the exhibition, we would seriously urge the duty of candidly considering its merits. If, as a Profession, we neglect or ignore this duty, we shall do an injustice to ourselves and to the public. If the remedy prove as efficacious as asserted, it will come into vogue with or without our leave or advice, and, in spite of us, we shall obtain the character of wilfully or negligently obstructing the progress of science. This is just one of those instances in which the public may take the investigation out of our hands; and yet we first of all ought to be prepared to say whether the proposed treatment be consistent with physiological science. It is not our intention dogmatically to pronounce for or against the treatment. Indeed, we are not accustomed to devote our leading columns to the advocacy of any therapeutical system, but we feel it only due to a most able physiologist to testify to the necessity of submitting his conclusions to the test of experience. No doubt many of our brethren who may cross to the channel to see the exhibition, or to be present at the Medical Congress, will be glad to avail themselves of the opportunity of trying the experiment, and those who may not be able to go themselves may as well give the necessary instructions to their patients. Thus, in a short time, sufficient facts may be accumulated to confirm the only really scientific theory which has been put forward, and that, be it remembered, a theory of the utmost significance in reference to other more important diseases, and which has been applied by its author to an elucidation of the pathology of cholera, epilepsy, paralysis, and other equally diverse conditions. The reader will of course have perceived, that the theory to which we allude is that of Dr. Chapman, whose reputation is not confined to professional subjects, and some of whose valuable physiological and medical contributions have appeared in our columns.

This being so, we need only, in the briefest manner, sketch the theory in question. Reasoning on the facts that had been demonstrated by Claude, Bernard, and Brown-Séquard, that a division of a portion of the sympathetic increased the flow of blood to the parts to which its branches are distributed, while galvanism of the nerve decreased the amount of blood in the same parts, Dr. Chapman directed his inquiries to the possibility of finding remedial agents that would depress or excite the action of the nervous centres. Such a depressant, he concluded, might be found in *cold*, while the opposite condition of *heat* should, *a priori*, act in a manner analogous to galvanism. Five years ago he put his conclusions to the test, by applying cold and heat to the spine, and so satisfied is he with the result, that he has not ceased during that time to urge upon the Profession his belief, that by varying the temperature of the nervous centres, we may, at will, diminish or increase the vital activity of those parts which derive their nerve supply from the portions on which we experiment. Reduced to its simplest and most practical form, the theory amounts to this, that we may vary the temperature of parts of the nervous centres, with the following effects:—By raising it, we increase the supply of blood to the part immediately acted upon, and thus exalt its activity; thereupon, increased nervous influence flows outwards, so that the nerves, distributed to the blood-vessels, stimulate them to contract more powerfully, and thus reduce the supply of blood. On the other hand, by decreasing the temperature, we diminish the blood-supply of the part operated on; this results in a diminution of activity, and so less nervous influence flows outwards, and the capillaries are allowed to dilate, such dilation, of course, admitting an increased quantity of blood in the part, and, as a consequence of this, giving rise to increased vital activity. In the same way as the sympathetic ganglia are acted upon by heat and cold, so, naturally, the spinal cord may be influenced in the same manner. The application of this theory to the treatment of sea-sickness, involves a consideration of the immediate cause of that distressing malady. Dr. Chapman is convinced that the "proximate cause of sea-sickness consists in an undue amount of blood in the nervous centres along the back, and especially in those segments of the spinal cord related to the stomach, and the muscles concerned in vomiting."

Dr. Chapman alleges that the pallor and coldness of the surface, characteristic of sea-sickness, are due to the contraction of the peripheral blood-vessels in the mode we have just explained; that the cold sweat, and the copious secretion of mucus often excited from the stomach, are due to excessive stimulus from the spinal cord, which he affirms to be the efficient cause of glandular action, and that, as is well known, the spasms of the voluntary muscles, proceeding, in rare instances, to convulsions, are also due to hyperæmia of the cord. This hyperæmia of the nervous centres is caused, as he maintains, by the motion of the vessel acting on the brain, the abdominal viscera, and the spinal column, and, if the theory be correct, it is obvious, that by preventing the hyperæmia, we take away a segment of the circle, which must be complete in order to produce the disease. This he does effectually, if we may trust the reports of cases, by the application of ice along the spine.

---

RETURN of the number of Assistant-Surgeons (excluding Household regiments) borne on the strength of the British Army on the 19th day of March, 1867.—T. G. Logan, Director-General.

## Notes on Current Topics.

**THE PRINCESS OF WALES.**—The medical gossips of London have been busy during the week with a variety of speculations respecting the probable effect of the late cold weather on the Princess of Wales. Every medical man is aware of the anxiety with which invalids and those who surround them are accustomed to regard everything which may affect the prognosis of the case, and we cannot feel surprised that such should be the feelings of the general public respecting Her Royal Highness. No material change has taken place since our last report, and the limb necessarily continues to be kept in absolute repose. The only element that can be called new since our last account is that of time, and as to that our readers will be able to decide for themselves how far the continuation of inflammation in the knee-joint for that period threatens a permanent loss of motion.

**SIR WILLIAM LAWRENCE.**—Some improvement has taken place in the condition of this learned surgeon. One of his first acts after the seizure was to resign the Examinership of the College of Surgeons. Mr. Solly, of St. Thomas's, is likely to succeed. It may interest our readers to learn—as an instance of Sir William's extraordinary tenacity of work—that the day before his seizure he was at Bethlehem Hospital, and appointed the next day to perform an operation on one of the inmates. Those in charge were somewhat anxious on account of some delay in the preparations lest they should not be ready for the punctual surgeon, and were rather pleased at finding him behind time. Of course they learned later the reason he was not there at the time appointed. He continues under the care of Dr. Tweedie and Sir Thomas Watson.

**THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—We understand that the Examiners of the College are about to introduce a Practical Clinical test in Surgery into their examination, and with this object have asked permission from the managers of the Metropolitan Hospitals to examine in their surgical wards.

**THE International Ophthalmological Congress,** which was to have taken place in Vienna in August, 1866, and was postponed on account of political events, will be held this year in Paris, on August 12, 13, and 14. A preparatory meeting will be held at the house of the President, M. Sichel, 50, Rue de la Chaussée d'Antin, at eight o'clock, on August 11.

**THE ENGLISH POOR-RATE RETURN.**—The Poor-law Board has issued its annual return, from which it appears that the amount of poor-rates levied in the year 1865-66 was £9,573,772, and that the receipts in aid from other sources brought the total up to £9,958,250. Of this sum only £6,439,517 were expended for the relief of the poor, for in-maintenance, for out-door relief, for lunatic in asylums, workhouse loans, salaries, and other expenses connected with relief. All the items are larger than they were last year, except out-door relief. This exception was owing to the distress in Lancashire and Cheshire having subsided considerably since that time. The expenditure for out-door relief for all England constituted 49·7 per cent. of the total relief, but in the metropolis only 23·9 per cent.

**CHOLERA.**—Will the epidemic return this summer? To the indications already chronicled we may add that in the East, and particularly about Scutari, a tendency to spread has been noticed. Since the doubtful case or two that appeared in the weekly returns of London, several suspicious cases of alvine flux have been admitted to the metropolitan hospitals. In some of the Paris hospitals decided cases of cholera have been admitted lately. An Italian correspondent assures us that the Peninsula is not free from the scourge. These facts should suffice to set all our sanitary authorities to work. Are we better prepared to meet the enemy than we were last year?

**THE COMMISSIONERS OF NATIONAL EDUCATION AND SANITARY SCIENCE.**—Some months since the happy idea occurred to Dr. Cullinan (the chairman of the Ennis Town Commissioners), of procuring the circulation, as a reading-book or lesson-book, in the national school, of a manual of Sanitary Science. The body to which he belongs at once brought the matter under the notice of the National Education Commissioners, but nothing resulted until Captain Stackpoole moved in the House of Commons for copies of the correspondence. It then appeared that the Ennis Commissioners urged that the elementary treatise should be written by some accredited writer, and they suggested the names of Drs. Sutherland, Lankester, and Mapother. The Education Commissioners alleged that they were already preparing, with the aid of their own staff, a manual of Sanitary Science. Such has not yet however appeared, and the public has a right to demand that it shall be carefully prepared, and shall both, in accuracy of detail and simplicity of diction, meet the requirements of the pupils of our elementary schools. If the production of the Commissioners be deficient in these respects, we shall not fail to denounce the policy of trying to save expense, or seeking to aggrandize profits to their own staff, at the risk of that missing scientific accuracy and popular mode of expression, which this novel hand-book should eminently possess.

**THE EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS OF IRELAND.**—The Quarterly Examinations, which have just closed, have been conducted under a new arrangement, which has, on its first trial, proved eminently satisfactory as a test, and at the same time just to the candidate. Hitherto each of the Examiners has voted by "yes" or "no" on the passing of the candidate, and the majority of votes carried the decision of the Court. By a late ordinance of the Council this arrangement has been superseded, and the plan of voting by numbers substituted for it. The four Examiners are placed at separate tables. A candidate, accompanied by a member of council, takes his seat at each table. The examination lasts for a quarter of an hour, and, at its conclusion, the Examiner hands the Councillor his written vote, and the candidate passes on to the next. When the examination has terminated, the candidates leave the room, and the numbers of each are declared. The maximum number which any candidate can obtain from each Examiner is 15, or a total of 60 from the four Examiners. The minimum is 0, and if the gross marks of a candidate should not reach 20, he is referred back to his studies. Under this arrangement, 46 students have presented themselves at the first half of the examination, of whom 39 have passed, and 7 been rejected; and 22 for the second half, of whom 3 were rejected.

THE PRELIMINARY EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS OF IRELAND.—At a meeting of Council, held on May 15th, the following resolution was passed, viz. :—“That the answering at these examinations be arranged as follows :—1st. Class certificate ; 2nd. Class certificate ; 3rd. Passed, but not classed. That the Examiners be empowered to recommend successful candidates for the two first of these honours, and that a special certificate, under the authority of the Council, be granted to them, which should be signed by the President or Vice-President, the Secretary of the College, and one of the Council.

THE REPORT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.—The College held its annual meeting on Monday last to receive from the Council their report of the proceedings of the past year. The chair was occupied by the President, and there was a large attendance of Fellows and Councillors. In its own body the council has had several changes in consequence of the resignation of Dr. Arthur Jacob from his professorship, and from his seat as a councillor. Dr. Mapother, who was elected last June, of necessity vacated his seat in competing for the professorship of anatomy and physiology. In his place Dr. W. A. Elliott was chosen to serve, and on the resignation of Dr. Arthur Jacob, his son, Dr. Archibald H. Jacob, was elevated to the seat. The roll of attendances show that the council consider their position as a paramount claim on their time, for, with the exception of those gentlemen who were elected at a late period, or were debarred by ill-health, the attendance of members has been creditably regular. During the past year 16 Fellows, 104 Licentiates, and 11 Licentiates in Midwifery were added to the roll of the College, while 27 candidates were rejected in the junior, and 10 in the senior class examination. The College now possesses a roll of 2186 Fellows and Licentiates—a constituency many times greater than that of certain parliamentary boroughs. From the financial statement it appears that the College is in a flourishing condition, a sum of £700 having been lodged in bank, while a further balance of £400 remains to be carried forward to next account.

#### “THE CARMICHAEL PRIZE ESSAYS.

“At a meeting of Council, held on December 10, it was resolved—

“That Mr. Litton, the solicitor of the College, be authorized to consult Mr. Lawson, Q.C., respecting the enlarging of the subjects of the Carmichael Prize Essays.”

“At the same meeting it was also resolved :—

“That the usual notices be given on Monday next, in the public prints and medical journals, for the reception of Essays for the Carmichael Prizes, subject to the conditions of the testator’s will.”

#### “THE BRITISH MEDICAL ASSOCIATION.

“At a meeting of Council, held on August 2, it was resolved—

“That the Council having learned that the British Medical Association intends to hold their anniversary meetings for 1867 in Dublin, it is resolved, “That the Secretary be directed to write to the Secretary of the Association, to inform him that the halls, libraries, and museums, and lecture rooms of the College, shall be thrown open for their accommodation.”

#### “DR. JACOB’S RESIGNATION OF THE PROFESSORSHIP OF ANATOMY AND PHYSIOLOGY.

“At a meeting of Council, held on January 15, the following letter was read, viz. :—

‘Croydon, 13th January, 1867.

‘GENTLEMEN,—Being convinced that I cannot with confidence rely on my power to deliver the Lectures on Anatomy

and Physiology next Session in the College School, I think it will be more for the good of the College and the benefit of the pupils, that I should resign my Professorship now, which I hereby do accordingly, after fifty years’ service as an anatomical teacher, forty of them as the Professor of Anatomy and Physiology in your College. You will, I am sure, agree with me that the period has arrived for the performance of this act.—I have the honour to be, your very obedient servant,

‘A. JACOB.’

“Proposed by Dr. Hargrave, seconded by Dr. Adams, and unanimously resolved—

“That we, the Council, having received a letter from Dr. Jacob, resigning the Professorship of Anatomy and Physiology, which he held for so many years with so much honour to himself, credit to the College, and educational advantages to the numerous students who have pursued their studies in the College School, it is with feelings of deep regret we accept it.”

#### “DR. JACOB’S RESIGNATION OF HIS SEAT ON THE COUNCIL.

“At a meeting of Council, held on March 7, the following letter was read, viz. :—

‘March 5, 1867.

‘MR. PRESIDENT AND GENTLEMEN,—Being assured of the benefit which I derive from complete physical and mental relaxation at my present place of residence, I have determined, on due consideration, to relieve myself permanently of active professional labour.

‘Feeling, under these circumstances, that I ought not further occupy the position in the administration of the College with which I have been so long honoured, I beg to lay before you my resignation of the office of Councillor.

‘It may be believed that I have decided on this course with much anxiety for the maintenance of those interests which I have so long endeavoured to sustain, and with much regret at a separation from my colleagues, who have so friendly and cordially acted with me in upholding those principles which I now leave with confidence in their hands.

‘In retiring from personal connection with the Council of the College, I cannot divest myself of the interest which I have taken in its affairs, and it will afford me much satisfaction if, by any means of communication, I can make available such information as my long official relation to the College has enabled me to acquire.—I have the honour to be, your grateful and sincere friend and Fellow,

‘A. JACOB.’

“The election having been held as above, Dr. Archibald H. Jacob was duly elected a Member of Council, in room of Dr. Jacob, resigned.”

#### “TESTIMONIAL TO DR. ARTHUR JACOB.

“At a meeting of Council, held on February 21, it was resolved—

“That it be referred to the Finance Committee, and report to the Council as to the best means of expressing their sense of the benefits conferred on the College and the School by the long, eminent, and successful services of Dr. Jacob.”

“In accordance with the foregoing resolution, the Finance Committee brought up the following report on March 7 :—

“Your Committee, anxious to give effect to the wishes of the Council, recommend an address be presented to Dr. Jacob, to express their regret that the state of his health has compelled him to resign the chair of Anatomy and Physiology, and his seat on the Council, which he has so long filled with credit to himself and the College.

“That a portrait of Dr. Jacob be placed in the Board-room of the College.

“That a piece of plate, not less value than one hundred guineas, be presented to Dr. Jacob, as an additional testimony of respect and gratitude for his services.”

“The report having been read and unanimously agreed to, it was proposed by Dr. Colles, seconded by Dr. Hargrave, and resolved—

“That the Finance Committee be empowered to carry the resolutions in the report into effect, and to give such publicity to the same as they may think fit, subject to the approval of Council.”

“At the same meeting it was also resolved—

“That Mr. Catterson Smith be engaged to paint a three-quarter portrait of Dr. Jacob for the College.”

"At the same meeting the following address, about to be presented to Dr. Jacob, was read, agreed to, and ordered to be engrossed and signed by the President, Vice-President, and the Members of Council:—

'SIR,—We, the President, Vice-President, and Members of Council of the Royal College of Surgeons in Ireland, beg leave to express to you our sincere regret at the loss we have experienced by being deprived of your valuable services in the conduct of the business of the College, and in the teaching in the School attached thereto.

'We are fully sensible of the great amount of time, talent, and labour you have so long and so disinterestedly devoted to advancing the best interests of the College, to maintain its privileges, and to enlarge its sphere of usefulness.

'We also gratefully acknowledge that your exertions in teaching the important subjects of Anatomy and Physiology, during a period of more than forty years, have materially conduced to the success of our School, whilst your contributions to Science have made your name illustrious amongst those who have enriched our art, whereby you have enhanced the fame of Irish Surgery.

'We earnestly hope that your life may long be spared to enjoy the well-merited repose which voluntarily you have sought, and are anxious that you should bear with you the satisfaction of knowing, that the College is deeply grateful to you for your earnest, long-continued, and successful labours in its behalf.'

"TO THE PRESIDENT, VICE-PRESIDENT, AND MEMBERS OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

GENTLEMEN,—I have had the pleasure of receiving your very kind expression of regret at the loss of my services in the conduct of the business of the College and the teaching in the School, as well as your expression of belief that my labours have been disinterestedly devoted to advancing the best interests of the College, to maintaining its privileges, and enlarging its sphere of usefulness.

"If I have been successful in my endeavours to accomplish these objects it has been owing to my firm reliance on the judgment and independence of the Council, supported as it is by the Fellows at large, and therefore am I convinced that the College will continue to flourish as heretofore, notwithstanding the change to which these observations refer.

"Allow me to add, that although I can no longer discharge the duty of Councillor, I shall at all times, as long as I live, be prepared to place my services at the disposal of the College, be their value what they may; and so I remain your friend and colleague,  
A. JACOB.

"PROFESSORSHIP OF ANATOMY AND PHYSIOLOGY.

"At a meeting of Council, held on February 21, Dr. Mapother was unanimously elected Professor of Anatomy and Physiology in the School of the College, in room of Dr Jacob, resigned.

"PROFESSORSHIP OF BOTANY.

"At a meeting of Council, held on March 21, 1867, Dr. Minchin was elected Professor of Botany in the School of the College, in room of the late Dr. Arthur Mitchell."

### CHORLTON UNION HOSPITAL.

WE have several times mentioned the magnificent hospital lately built by the Guardians of the Chorlton Union. Mr. T. Worthington has forwarded us a pamphlet, with plans, comprising his account of it recently read before the Manchester Statistical Society, and which shows him to be a correct writer as well as an able architect. The population of the Chorlton Union has now reached 180,000, and the large workhouse hospital, built only ten years ago, has already become too small—a clear proof of the rapidity of increase in the population of this part of the kingdom.

The building just erected is on the pavilion plan, and consists of five oblong blocks or pavilions, connected at the southern end by a long, open, arcaded corridor, forming a means of communication between them all.

This building was commenced in 1864, and is now in full working order. Mr. Worthington seems to have de-

voted all his energies to the work, having, in order to place himself in the best position to acquire information, visited some of the largest European hospitals.

The result does him infinite credit, and we cannot do better than avail ourselves of the information contained in the pamphlet before us:—

"Each pavilion is three stories in height, and contains on each floor a ward 124 feet long, and 24 feet wide, with beds for 32 patients. At the southern or entrance end are a spacious open staircase, a nurses' room 12ft. x 11ft., a ward scullery 12ft. x 10ft., a water-closet for the use of the nurse and attendants, and a hoist to raise food to the upper stories; at the northern end of the wards are two small projecting wings, one of which contains two water-closets for the patients, a sink for cleansing the bed-pans, and a closet for brushes, &c.; the other contains the bath-rooms, lavatories, dust shoot, foul linen shoot, &c., &c.

All the above accommodation is repeated on each of the three floors; so that there are, in each pavilion, three wards of 32 beds each: making a total of 96 beds in each of the five pavilions, or 480 beds in all, with the several minor rooms just enumerated.

The heights of the wards are as follows:—

	14ft. 6in.	clear ground floor.
	14ft.	" first "
Average	15ft.	" top "

The top ward is somewhat higher than the others, being partially in the slope of the roof.

The number of cubic feet of air space to be allotted to each patient, being of the first importance, was a subject of the most careful and anxious consideration.

The Chorlton Guardians discussed this point at great length. All thought of adopting the old standard was abandoned. It appeared desirable that such an air space should be allowed as would be likely to effect the most expeditious cures, and the most rapid removal of cases from the parish books.

It was ultimately determined that each inmate should have an air space of 1350 cubic feet or thereabouts, which is more than double the minimum space required by the Poor-law Board, and about three times that allowed in several of the larger Metropolitan workhouse hospitals.

In the east and west walls, or the long sides of the wards, are placed a series of large windows 4ft. 8in. wide, and extending from 2ft. 9in. above the floor to the ceiling. These windows are in all cases facing one another, and are divided in their entire height into three sub-divisions.

The lower portion, for about three-fourths of the whole opening, consists of an ordinary double-hung sash; the upper fourth is pivotted, and works on a swivel with cords, to open at any desired inclination. On the top of this swivel-light, and, in fact, forming a portion of it, is a continuous hopper-shaped frame, made of cast iron. This frame extends the entire width of the window. It is glazed at the front and ends, but a space at the top is left open about two inches wide and the full length of the frame. This long narrow opening is covered with fine wire gauze, and admits a constant but imperceptible stream of the outer air, which is continually passing across the ward close to the ceiling, towards the corresponding opening in the opposite window. A slightly upward direction is given by the sloping form of the hopper, in order that the air may be thrown towards the centre of the apartment, and be so distributed as to avoid down currents.

Any or all of the three divisions may be opened more or less, at the discretion of the attendant; but when all are opened to their full extent, the ward will in a very short time be flooded with fresh air.

Besides this, however, there is the opportunity of obtaining a current from the two extreme ends of the ward, and flushing the upper part with fresh air without opening the doors.

This is effected by means of a glazed louvre, about 6ft. high and 4ft. wide, placed at the entrance end, over the door from the staircase; and at the other, or balcony end, by means of a large swivel window, similar in arrangement to those already described. The louvre, which is worked by a very simple mechanical contrivance with lever and screw, may be adjusted to admit more or less air as required, but practically they are very rarely closed.

There are also, at various points in the walls, air shafts or flues discharging above the roof level; and the ventilation is further assisted by a considerable number of small air grids or channels built in the walls, at short intervals, close to the ceiling. These

grids have a sloping lip on the inside, projecting about five inches from the wall, with an inclination of about 45°, to prevent the air falling at once in a cold volume to the lower part of the ward. A corresponding grid is placed in the opposite wall in each case, and the air appears to take a direction generally across the ward, near to the ceiling. The air being thus admitted in very small quantities and at very numerous places, diffuses itself without perceptible draughts, and displaces the gaseous portion of the contained air which naturally rises to the top.

The form of the small air channels is such that they would hardly be observed if not pointed out, and are therefore not likely to be wilfully obstructed; especially as they are close to the ceiling, and therefore out of reach.

In the floor of each ward, at a distance of six feet from the outer walls, are a number of hit-and-miss gratings, with galvanized iron horizontal tubes or flues, to conduct the fresh air to the foot of the beds, should it be required in foul cases, or when it may not be desirable to open the windows.

On the ridge of the roofs are revolving ventilators of large diameter, to promote the ventilation of the top wards, which are partly in the roof, so that the windows do not reach the highest part of the ceiling.

Each ward is lit at night by three suspended rings of gas-burners, over which a funnel-shaped cowl is suspended, which terminates in an iron flue communicating with a shaft in the wall, by means of which the products of the gas are carried off, while at the same time an upward current is caused and a further impulse given to the ventilation during the night, when the windows are usually closed.

The warming is effected entirely by means of large open fire-places, three in each ward.

The water-closets are contained in the left wing, and are extremely simple in construction and very inexpensive. The entire basin and seat are of earthenware, without wooden seats or fittings. The cleansing is affected by means of a chain attached to the door, which raises the valve and flushes the basin each time it is used.

A sink or trough for emptying the bed pans adjoins, and has a similar earthenware basin with a lead receiver on the top, flushed by means of a hand-pull. The divisions between the closets are of sawn slate slabs about seven feet high, with a frame-work of cast iron; non-absorbent materials generally have been used where ever possible in this department.

The baths are placed detached from the walls, so that a patient may be supported on both sides, are of Stourbridge fire clay, lined with a coating of porcelain, and the supply of water is constant. Hot water, though heated in the ward scullery at a distance of 140 feet, can at all times be obtained without drawing off cold stagnant water from the pipes. The divisions here, as in the water-closets, are of sawn slate. Adjoining are the lavatories, consisting of large earthenware basins with polished slate tables; and hot and cold water is always ready.

In one corner of this wing are taps of hot and cold water for washing purposes, and for filling the portable baths; and a two-inch fire-plug and hose are fixed in this wing on each floor.

Here also are the dust shoot and the foul linen shoot: the former of cast-iron, with hopper and door on each floor, discharging into an ash-pit outside the building; and the latter of wood, discharging into a ventilated chamber in the basement. These two shafts adjoin, and are carried up about 8 feet above the roof, with a revolving ventilator 2 ft. 6 in. diameter on the top, to prevent any foul or stagnant air accumulating in the shafts.

The Manchester Corporation convey the water to the work-house by a special 7-inch main, which entirely surrounds the whole of the hospital buildings, having fire-plugs placed between every pavilion, both at the northern and the southern ends, besides in other convenient positions, and the pressure from the mains is sufficient to reach to the roof in case of fire. Ten tanks, one on the top of each of the wings just described, each containing 2500 gallons of water, are supplied by rising mains 3 in. in diameter: so that when filled, 25,000 gallons of water are stored for the use of the hospital.

The hot water apparatus has been contrived with great care, and is ingeniously arranged on a plan suggested by Mr. Ward, the contractor for this part of the work. The boiler and hot water reservoir are in the small ward kitchen on the ground floor, and the hot water piping is carried, as before mentioned, to the wing containing the baths and lavatories, a distance of about 140 feet. The whole of these pipes are wrapped in thick

coarse felt to prevent frost having effect on the water; and the entire system of piping may be emptied in the basement in case of repairs or extreme frost.

The drainage is entirely outside the buildings; and in no case is a drain brought within the walls, except to receive the descending soil pipes or waste water pipes. It is throughout of glazed earthenware.

In the three principal chimney stacks in each of the five pavilions there is a special flue built, discharging above the roof, to which the drains are connected for ventilating purposes. This flue is entirely independent of any other, but is placed between two smoke flues, which by their heat cause an upward current in the intermediate flue, and by this means the drainage is ventilated at 15 points. On the top of these flues charcoal boxes will be placed, to destroy any gases which may rise from the drains.

The food hoist or lift is in the staircase adjoining the ward sculleries. It is constructed on a very simple principle, and works with great precision. It is provided with a break, so that the lift may be checked at any required point.

The cost of the five pavilions with the corridor, as above described, including the gas and water supply and the various fittings referred to, has barely exceeded £23,000.

## HARVEIAN SOCIETY OF LONDON—MAY 9.

Dr. J. E. POLLOCK, President.

### THE PREVENTION OF VENEREAL DISEASE.

PRESENT:—Mr. W. Cooke, Mr. Acton, Dr. V. Bazire, Mr. Curgiven, Dr. Chas. Drysdale, Dr. Tilbury Fox, Mr. G. Gascoven, Mr. J. Lane, Dr. Maudsley, Dr. Meredyth, Mr. Sedgwick, Dr. Steele, Mr. Teevan, Dr. M'Loughlin, Dr. Beigel, Dr. Hjaltekin, and Dr. Vintreas.

Reports were read by the Honorary Secretaries as follows:—  
Mr. Square reports from University College Hospital, that the average daily number of venereal cases seen there, is 9; in the proportion of 1 to 3.3 of the total number of surgical cases seen. Venereal patients are not admitted into the hospital.

Mr. Moore reports from St. Mary's Hospital, Paddington, that the daily average of venereal patients at that hospital is 14, or about one-fifth of the surgical out-patients daily seen. "Saint Mary's Hospital does not profess to treat venereal disease." There are no beds for such cases in that hospital.

Dr. Nankivel reports, that at the Chatham General Hospital, there are no male venereal beds, but 40 female lock-beds under the Contagious Disease Act. He adds, "my appointment dates from Christmas, 1866. The following results I have taken from my own out-patient book. The total number of fresh entries in my out-patient book, for the quarter ending March 31st, 1867, amounted to 527, of which 133 were surgical, and 35 were venereal, according to the definition supplied in this form. I shall be happy to see the Honorary Secretaries of the Harveian Society, if, at any time, they should desire to prosecute the inquiry on the spot."

Mr. Vincent Jackson reports from the Wolverhampton General Hospital, that there is a daily average of 11 venereal patients seen at that hospital, or about one-sixth of the strictly surgical cases. No beds are set apart for venereal diseases.

The report from the West London Hospital gives a daily average of 5 male and 3 female venereal patients, or about 1 in 8 of the surgical patients. There are no beds for venereal cases.

The report from the City Hospital for Diseases of the Skin, shows that in the month of April, there were 17 new cases of syphilitic disease seen—10 males and 7 females, or one in 8 of the new cases seen during that month.

Dr. Rayner reports from the Islington Dispensary, that "as patients are only admitted by Governors' letters, distributed personally, a case of venereal disease is a rarity. Not more than forty such cases came under treatment in a year."

Mr. W. Smith reports from Portland Town Free Dispensary, that it is "one of the rules of the institution, that no one afflicted with venereal disease can be admitted as a patient."

Mr. R. W. Dunn reports, that of 1280 surgical cases seen by him at the Farringdon Dispensary, 159 were venereal—60 males and 99 females, that is, 1 in 8 of the cases seen by the Surgeons.

In a letter from Mr. Spencer Smith, that gentleman says, "the only part I could have taken in your proceedings would have been that of congratulating the Committee of the Harveian Society, (and, therefore, the Venereal Disease Committee),

upon the advanced views which they have so decidedly adopted with regard to prostitution."

In reply to circulars sent by Mr. Curgenvin, Mr. Thornburn, Secretary to the Medical Section of the Royal Manchester Institution, Mr. John Cardell, of Salisbury, and also the Secretary of the Southampton Medical Society, sent letters to signify the readiness of the several Medical Societies of these towns, to co-operate with the Committee of the Harveian Medical Society.

Dr. DRYSDALE said that he regretted that there were no reports as yet from the King's College Hospital, from St. Thomas', from London Hospital, from St. George's, Charing-Cross, or Westminster Hospitals. He hoped that the insertion of this fact in the journals would obtain the desired returns. The report, too, from the Middlesex Hospital, was very imperfect, and merely said, that "a correct reply was impossible, without much labour devoted by all the medical staff, the cases being dispersed all over the wards." There are eleven venereal beds in the hospital.

Mr. ACTON said that not many years back, no venereal cases were admitted either into the Middlesex or the London Hospitals, and in the former, payment was exacted when such cases were treated in former times.

The PRESIDENT hoped that the reports from the Middlesex and London Hospitals might soon be obtained.

The following extract from a letter from Dr. Steele was read, dated

"Guy's Hospital, 9th April, 1867.

"I have made some inquiries with the view of aiding your object, and will detail to you, in the rough, what results I have been able to obtain. You will observe, from my last year's report, that there were nearly 60,000 out-patients treated at Guy's. Of that number, 36,600 were enrolled as ordinary surgical cases; 14,800 as ordinary medical cases; 2500 as diseases of the eyes; 700 as diseases of the ear; and 700 diseases of the skin; while the remainder was made up of cases which could have no possible connexion with venereal diseases—to wit—minor accidents, tooth extraction, and midwifery cases. The relative number of venereal cases to the ordinary surgical cases is very large, averaging, from the opinions of the assistant-surgeons, not less than two-thirds of the total number daily seen, or 24,000 of the cases entered under this heading. I am informed that, amongst what are termed ordinary medical cases, the estimated average is not more than five per cent.; among diseases of the eyes, ten per cent.; and of the ear, about five per cent.; among diseases of the skin, four-fifths of the cases are attributable to venereal taint, whilst amongst the diseases peculiar to women, examined by the physician-gynaecologist, I am informed that those are not less than ten per cent. connected more or less with these diseases. This would give a rough total of 25,800 cases of venereal diseases treated in the out-patient department in the course of the year, or forty-three per cent. of the total number of persons entered on the books. With regard to the in-patients, my answer refers only to patients suffering from syphilis, who are placed in the venereal wards. There are, doubtless, many more in the hospital suffering from sore-throat, caries of the bones, rheumatic pains, &c."

Dr. STEELE observed that the remarks made in the above letter were only true in the rough. It would require several weeks to make them more accurate.

Mr. WEEDEN COOKE remarked on the extreme frequency of venereal diseases in Guy's.

Mr. ACTON said that when he formerly made some inquiries, he found the proportion to be nearly one-half venereal cases to all surgical out-patients in St. Bartholomew's Hospital.

Dr. DRYSDALE said that the proportion at the Royal Free Hospital was put down as three to eight; and at the Metropolitan Free Hospital, as one to three of the surgical out-patients; but Guy's was the heaviest proportion.

Dr. MACLOUGHLIN begged to ask the Committee whether he might be allowed to state his opinion that there was no such thing as a contagious venereal disease. He believed that there was no such thing, and that the eruptions called syphilis, and the discharge called gonorrhœa, had nothing to do with contagion, but were accidental.

Mr. ACTON said that, as the Committee were all of opinion that there were such diseases, he hoped that the President would not have this question discussed, as he was obliged himself to leave soon, and wished to say a few words on the matter of police registration before he left.

The PRESIDENT observed that, as this Committee were assembled for the express purpose of endeavouring to check the amount of contagious venereal diseases in this country, it was

evident that Dr. MacLoughlin's question was taken for granted by the Committee, and therefore could not be discussed.

Dr. MACLOUGHLIN said that he had been invited to attend the Committee, and, as he was not to be allowed to discuss this fundamental point, he thought it needless to remain. He therefore begged to retire.

Mr. ACTON then said that he could not help thinking that the Committee should not be in too great a hurry to carry out the Contagious Diseases Act of 1866 among the general public, as the majority had decided to do. The most important duty of the Committee should be to collect, as they were doing, statistics sufficient to show the enormity of the evil, and the necessity for something being done. It was by no means certain that objections to the Government measure would not soon be heard of, even among military circles. He thought the Committee too much ignored the religious party. There was a religious party who only, he believed, wanted a case to take up and make an outcry about, in order to prevent the Contagious Act being carried out. He had had much experience of that party. Would it not be better to pause a moment before committing themselves to any decided measures. Were the results so remarkable in the army?

Mr. JAMES LANE said that the results of the Army Act were already admirable. Although the Act had only come into operation in October last, the amount of disease at Woolwich, was only half already of what it had been, and consisted, in a large proportion, of cases of gonorrhœa. The examinations as yet had been confined at Woolwich to the women suspected of being diseased. No objection was made by the prostitutes. He believed, of course, that the matter would be by no means so simple in London.

Dr. BEIGEL said that he had heard, with surprise, the reports from so many hospitals and dispensaries, stating that venereal disease was not treated in such hospitals. So long as this was the case, it was no wonder that the diseases were so common as they were in London. He (Dr. Beigel) had been for many years connected with the Charité Hospital of Berlin, during the lifetime of Dr. Baerensprung, and he must say that the forcible examination of women had not seemed to him so beneficial as was supposed by many. Some of the women were nearly all the year in hospital in Berlin. They went out for a time, got fresh infection, and came back; but not before they had infected many in the interval. In his opinion, facility of admission into hospital was the most important measure to be initiated, and was far more important than forcible examinations and registration which, as before said, his experience did not warrant him in recommending very greatly.

Mr. ACTON asked how long it took in many instances to cure gonorrhœa in a woman. Three months in many cases are not enough, and after that, even, she would infect a man. He was not so anxious as Dr. Beigel, either, to increase the number of venereal beds. This would cost too much to be entertained. The great point was to show the frequency and importance of venereal diseases to the public. As to the carrying out of the police examinations of prostitutes, one fact would show what might happen, and might raise an outcry which would retard the question indefinitely. When in Paris, a year or two ago, he attended the police examinations, when a young woman was brought in to be registered. She was a virgin, and the Committee could quite understand what an alarm would be raised if such a case took place in London.

Mr. JAMES LANE said that the Committee had determined not to make the examinations similar to those on the Continent. It might be true enough that in some cases gonorrhœa could not be cured under less than three months; but in most cases the discharge ceased in three weeks or so. It was only, however, by the speculum that the health could be known to be good.

The PRESIDENT asked Mr. Acton whether it was not true that the troops in Belgium were almost free from disease, whilst the English troops were most severely affected with venereal disease. Was not this an argument for police supervision of prostitutes?

Mr. ACTON replied that this was quite true, and in 1859, when he inquired, out of 3500 troops quartered at Brussels, there were only 11 cases of venereal disease; whilst out of 600 Fusilier Guards in London at that epoch, there were no less than 64 cases.

Dr. DRYSDALE said that the Committee had, with the exception of himself and Dr. Chapman, already voted in favour of registration and forcible examination of prostitutes.

Dr. FOX said that the Committee's object was the prevention of venereal disease, not the regulation of prostitution.

Dr. MAUDSLEY said that, without forcibly examining notorious prostitutes, nothing could be done towards the prevention of venereal disease.

Dr. HJALTELIN, Superintending Medical Officer of Iceland, said that there were in Iceland, with a population of 70,000 persons, neither prostitutes nor any venereal disease. All prostitutes were summarily shipped off when they came to the island. Of course this was not a practice which could be imitated by other countries.

Dr. BEIGEL said that women were liable to punishment for infecting men in Germany.

Mr. W. COOKE asked if this held good for men too.

Dr. BEIGEL thought not.

Mr. SEDGWICK observed that it would be of great importance to find out the amount of venereal disease treated in metropolitan workhouses. He believed from experience that it would be found to be very large.

Mr. CURGENVEN said the Committee hoped soon to obtain returns from the workhouses.

Mr. WEEDEN COOKE said that this was the largest of the questions raised. At the Royal Free Hospital they were inundated with poor diseased women from the workhouses. He wished to know whether these cases were treated at all at the workhouses, or were they neglected? He believed the latter.

Mr. SEDGWICK said that the latter view was correct. Women with venereal disease were looked on by the workhouse authorities as having forfeited their right to relief, and were thus sent from pillar to post, infecting right and left, until received into some of the more generous hospitals.

Dr. CHARLES DRYSDALE said that the result of the observations of Dr. Beigel, Mr. W. Cooke, and Mr. Sedgwick, and the reports which he had read from various dispensaries and hospitals, had convinced him how ill-judged the system was at present pursued in many institutions, with regard to the admission of the important class of contagious venereal diseases. What avail would any superintendence of prostitutes be, so long as there was no room for treating diseased persons, and no inclination to do so, save in the hospitals of Guy's, St. Bartholomew's, the Lock, and the Royal and the Metropolitan Free Hospitals, with a few others? He therefore proposed this motion: "That this Committee is of opinion that the present bye-laws obtaining in some of the hospitals, dispensaries, and workhouses of London, and other cities in this country, and which prohibit the entrance into hospital or treatment of venereal diseases, tend greatly to spread contagion, and ought, if possible, to be altered." Perhaps the opinion, if adopted, might act morally on the authorities.

Mr. TEEVAN seconded the motion, since it might perhaps stir up the members of various hospital staffs to represent to the governors the necessity of erasing such bye-laws. Every one knew that in many hospitals no venereal case is allowed to remain, if known to the Committee, and, until any general provision was made for diseased prostitutes, by the proposed extension of the act of 1866, he thought the passing of such a resolution desirable. Another remark he would make was, that it was ill-judged in the army authorities to force soldiers to enter hospital when affected with venereal disease, because they were confined and put on spoon-diet, the consequence of which was that when he was house-surgeon to University College Hospital, a number of soldiers from Knight's-bridge came to consult him, instead of going to their own surgeons, and these men said that it was common for men to consult chemists, &c., in order to avoid being sent into hospital.

Mr. JAMES LANE opposed the motion as being almost a stultification of the motion passed on the last meeting. If the Contagious Diseases' Act were extended to the community, one of its provisions would secure sufficient beds for persons with venereal diseases.

Dr. STEELE also opposed the motion. Many governors would not subscribe to charities if venereal patients were admitted.

Mr. GASCOYEN said that with regard to what had fallen from Mr. Acton, he thought, in the first place, that public opinion had much changed of late, and secondly, that we stood much in need of hospitals for the treatment of venereal disease. It might be true that some cases of gonorrhœa would require three months to cure, but, on the other hand, as the case of the more formidable disease, syphilis, if condylomata were seen and attended to, all danger of infection could soon be put aside by treatment. The workhouse infirmaries at present were not large enough to receive venereal cases, whatever they might be made.

Mr. WEEDEN COOKE observed that provisions should be made in Mr. Hardy's bill for carrying out the provisions of the

act of 1866, as far as having sufficient beds for venereal patients.

Dr. C. DRYSDALE withdrew his motion as the sense of the meeting seemed against it. At the next meeting reports will be read from the *Dreadnought* and the workhouses, if received.

## IMPORTANT PROSECUTION UNDER THE MEDICAL ACT.

THE CASE OF R. J. JORDAN.

THE proceedings of the London College of Surgeons against Robert Jacob Jordan, on which we commented last week, have resulted by the magistrate fining the defendant £20—the highest penalty he could inflict. Notice of appeal was given, and a case was allowed for the Court of Common Pleas, although it may be doubted whether this course will be really pursued. We furnish our readers below with a summary of the proceedings:—

The defendant, Robert Jacob Jordan, of George-street, Hanover-square, appeared, in answer to a summons, before Mr. Mansfield, at the Marlborough-street Police-court, "for unlawfully pretending to be, and taking and using the name, title, and description implying that he was recognised as a surgeon."

The Hon. A. Thesiger was for the prosecution; and Mr. Keane, Q.C., and Mr. M. Williams (instructed by Mr. Edward Lewis), were for the defence.

There was a second summons taken out by the Royal College of Physicians, Edinburgh, for a similar offence.

Mr. Thesiger said this was not the case of a man who had merely infringed the statute by holding himself out to the public as possessing the proper qualifications, but a man who had been a member of two honourable societies—that of the Royal College of Surgeons in England, and the Royal College of Physicians in Edinburgh—from which he had been expelled, and then openly braved the Society by keeping open an anatomical museum, the description of which must shock every mind possessing a particle of feeling or propriety.

Mr. Keane—If the defendant is to be tried for these alleged crimes, let him be charged at once with them.

Mr. Thesiger—The magistrate had a discretionary power as to the penalty, and therefore, if he proved the facts he should lay before the Court, he trusted the highest penalty would be inflicted.

After some formal evidence as to the laws and register of the Royal College of Surgeons, and the membership of the defendant,

Mr. Thesiger then said that at the meeting of the Council a resolution was come to expelling the defendant as a member of the College.

Mr. Stone proved delivering to the defendant a letter, written by Mr. Balfour, dated the 27th April, 1863, to the effect that by direction of the president he had been removed from the list of members, and asking him to deliver up his diploma. He (Mr. Stone) removed the defendant's name from the list of members immediately after the meeting of the Council. He produced the medical register for different years with the name of the defendant in it; but the defendant's name did not appear in that for 1867. He asked the defendant to give up his diploma when he delivered the letter, and, thinking he might like, before doing so, to consult his friends, told him he would call again, and did so, but the defendant refused to deliver up his diploma, nor had he done so up to the present time.

Mr. Thesiger read a letter from the council, which had induced the council to pass a resolution to the effect that, in consequence of the defendant distributing certain books, and advertising in the papers his "*Vita Vitalis*," he was to be expelled.

George Russell, a detective serjeant of the City Police, said that in consequence of instructions he had received from Messrs. Wilde & Co., on the 3rd April he went to the defendant's house, and saw on the door "Dr. R. J. Jordan." He rang the bell, and the door was opened by a porter. He asked the porter whether there was a museum, and he said there was. He asked what was the admission, and the porter said "One Shilling," and the porter gave him a catalogue, and said the museum was on the first and second floors, and he went up. He saw a document which he believed to be a diploma. It was dated the 4th February, 1859, and signed with the names of Green, Arnott, and Smith, the names all apparently in different handwriting. As he was coming down from the museum he saw a gentleman he believed to be the defendant, but he was differ

ently dressed. He went again on the 5th April and saw the defendant. He asked if he had a work on debility, and he said he had, and that it was a shilling, and he purchased it. The defendant said if he would wait a short time he would give him a book of extracts from his larger work, and, after a minute's waiting, he fetched him the book produced, but he did not charge him for it.

In answer to Mr. Keane, the Witness said he did not go to the defendant's owing to nervous debility, although the defendant might have thought he did. He went by direction of the solicitors. All he said to the porter was, "Is this a museum?" The defendant said nothing to him about the diploma at any time. He did not affect to consult the defendant. He told him he thought he had a friend who suffered from debility. He asked the defendant the best time to see him, and his charge, and he said in the middle of the day, and his charge was £1. The "friend" was merely a fiction. The defendant did not draw his attention to any part of the books. He did not ask the defendant if he was a legally-qualified practitioner, neither did he say he was. The books had not been in his possession ever since. He signed them before giving them to the solicitors.

Mr. Thesiger said that was the case for the prosecution.

After some discussion the further hearing of the case was adjourned till Thursday.

On which day the Council for the Defendant, Mr. Keane, made a most able speech in reply to the evidence given on the preceding day of trial. He said, looking at the evidence, no case was made out within the statute. He commented strongly on the language used towards Mr. Jordan by Mr. Thesiger, which he contended was far beyond professional licence; pointed out that Mr. Jordan had been removed from the books of the College for four years, and that from that time to the present he had been committing the same offence—if an offence it was—without anything being done by the College of Surgeons. He wanted to know why that august body had been so sleepy for so long a time, and now had become so lively, as, in effect, to say to Mr. Jordan, "Pay us £20 for what you have been doing against the Medical Act." What was it that the College charged Mr. Jordan with? Why, that he had published what they said was a disgusting book. But he was here reminded of Swift's remark, "that the nicest men were usually the men of the nastiest ideas," and that remark might now be applied to the College of Surgeons. He had himself looked through the book complained of, and could not for the world see anything that was indecent in it. The book might be improved in style, no doubt, but it was less explicit in details than other medical books to which no exception had ever been taken—the work of Tissot, for instance—a book full of learning, but full of that kind of information that would be a hundred times more dangerous to young people than any of Mr. Jordan's publications. The learned council then entered upon a series of technical points, the effect of which was to range the objections under four heads—first, that the College of Surgeons had no power to expel a member in respect of matters on account of which they had removed the name of Mr. Jordan from the list of members; secondly, that, assuming they had power, their proceedings were irregular, and that no proper expulsion had taken place; thirdly, that the words of the section of the act did not comprise a case like the present; and fourthly, that even supposing that the act did, the fact of the diploma being left in the possession of Mr. Jordan for so long a period constituted such an acquiescence as brought the case within the ruling of "Ellis v. Kelly," and afforded ground for a belief in Mr. Jordan's mind that the expulsion of the College was an illegal act, and that he was consequently entitled to style himself, and was in fact, at the present time, a member of the College of Surgeons. He could not help animadverting upon the way the evidence had been got up. The College had sent a disguised detective to Mr. Jordan's house. He did not blame the detective, for that was his line of duty; but he did blame the College of Surgeons, and must describe their conduct as mean and unworthy of them. The College of Surgeons had elected Mr. Jordan after an examination, and had given him a diploma. There was then no question of Mr. Jordan's qualification, by education, to practise as a surgeon; but the College had thought fit to except to certain works, published by Mr. Jordan, and to his keeping a museum. They had, in the plenitude of their assumed power, struck Mr. Jordan's name from the register, and demanded back the diploma, with which demand Mr. Jordan plainly said he would not comply. Neither the books in question nor the museum had been

proved to contain anything indecent. No evidence whatever to that effect had been given, and therefore the conduct of the College of Surgeons was not regular in taking the steps they had taken. It had not been pretended that Mr. Jordan had held himself out as being on the register, and as taking fees under that title. If that could be proved, then Mr. Jordan might be indicted for obtaining money by false pretences, but no charge of that kind had been made, because it could not be sustained. These proceedings were only an attempt on the part of the College of Surgeons to get what they never had, the power of punishing a man by summary conviction. With respect to the refusal to give up the diploma, he maintained that Mr. Jordan was justified in doing this, as he believed that he had been improperly removed from the register, and that he considered their order to be a nullity. Mr. Jordan had a right to say he had done nothing derogatory to the dignity of the College or the profession, and therefore that the College had no right to remove him. Mr. Jordan had adopted a certain theory of medicine, and because he had been unusually successful he had excited professional jealousy, and hence the present proceedings. If the College wanted to get back the diploma, why did they not take legal steps? Why did they allow it to remain in Mr. Jordan's possession for so long a period? Mr. Jordan did not want the authority or licence of the College of Surgeons; he could do, and had done, without it. He had what that College had acknowledged by granting him this diploma, that of which no human power could deprive him—the ability and the necessary qualifications for practising the profession he had adopted. In conclusion, he contended Mr. Jordan had not pretended that he was on the register, or held any office which rendered registration necessary, and therefore that the case had not been made out.

Mr. Thesiger having argued the legal points raised in the course of Mr. Keane's speech,

Mr. Mansfield said he had listened attentively to the arguments on both sides, the charge against the defendant, brought by an important body, being that the defendant Jordan had falsely used the name and title of surgeon. It appeared in the course of the arguments, different Acts of Parliament and by-laws having been referred to, that the Royal College of Surgeons claimed and exercised certain powers. The case before him, to a certain extent, resembled cases that came before courts-martial, the accused being charged with doing something unbecoming to the profession, and the Court being called upon to decide whether the charge was sustained or not. It was stated that some charge had been made before the College of Surgeons. He did not go into the question of the charge being right or wrong. The College had decided that it was proved, and they exercised their power of dismissal. It appeared that in exercising this power, the person so dismissed became *ipso facto* deprived of the power of exercising his profession. If this was so, the matter became very simple. He must presume that the College of Surgeons was an authorised body, that they had power to make inquiries, and that everything they had done had been rightly done. He was to presume that Jordan had done something—that he had held himself out as a practising surgeon, he not being a surgeon recognised by law, namely—a member of the Royal College of Surgeons. Now, he apprehended, that whatever might have been Mr. Jordan's former position with respect to the College, his status as a surgeon was put an end to from the date of the resolution passed by the College of Surgeons. Whether they came to that resolution rightly or wrongly, he had not to determine. The fact stood uncontradicted—that the defendant Jordan did put into the hands of the witness Russell, certain books, in which he (Jordan) was described as a member of the Royal College of Surgeons, and as having a diploma. In doing this the defendant represented himself to be what he was not, and so far the charge was proved. He offered no opinion on the point whether the College of Surgeons had power or were right in dismissing the defendant; or whether the College, by a resort to a higher Court, could be compelled to reinstate him. But there could be no doubt that under the circumstances the defendant could not be recognised as a surgeon by law, and the judgment must be, therefore, against him. The defendant would have to pay the full fine of £20.

Mr. Keane asked for a case.

Mr. Mansfield consented to give a case for the Court of Common Pleas.

The College has discharged a duty to its members and the Profession in its prosecution of the notorious Robert Jacob Jordan. The state of the law has not empowered

them to do more than purify their body of the taint of such association, and the penalty of £20—which is the extreme punishment within the power of the Court—will probably have no effect in putting a stop to the infamous proceedings complained of. The proceedings in the case were simply a legal proof of the authority of the College to demand the return of the diploma, and evidence that the demand was refused, and that Jordan still represents himself as a member of the College. There was no defence or denial of the charge, and the appeal, of which notice was given, must be, we presume, on some point of law. The prosecution of the Royal College of Physicians of Edinburgh is fixed for hearing on Tuesday next.

The selection of Jordan as the subject for prosecution is a curious and instructive comment on the law as it at present stands. That person has laid himself open to the penalty simply by having at one time desired to acquire real professional knowledge. He is singled out for punishment because he was a Physician and a Surgeon; because he had pretensions to professional capacity; and if he had been as impudent a swindler as his colleagues who practice without any pretension whatever to competency, he would have escaped, as they have done, at the blind side of the law.

We offer this enigma for the solution of the Medical Council now opening its annual session in London; and we venture to press upon that body the enquiry as to whose fault it is that such is the case.

Nine years after the whip has been placed in their hands to scourge such jackals from preying on the public, it is found powerless in their weakened grasp.

#### OBITUARY.

##### DR. BLACK OF EDINBURGH.

THIS gentleman expired at his residence in Edinburgh on the 30th of April last. He had devoted a long and active life to the service of the Profession—commencing his professional studies in 1806, and being appointed an assistant-surgeon of the Royal Navy after the usual examinations in 1809. Twelve months afterwards he was sent to the West Indies in the *Raven*, sloop of war, as surgeon to that vessel, and at the end of the war was placed on half-pay. He then commenced private practice at New Stewart, but soon removed to Bolton, in Lancashire, where he was appointed one of the physicians to the Infirmary and Dispensary. Here he remained till 1839, when, for family reasons, he settled in Manchester, and was chosen Physician to the Manchester Union Hospital, and Lecturer on Forensic Medicine in the medical school. Some years after this he returned to Bolton again, and as years increased upon him, he retired altogether from practice and spent his last years at Edinburgh.

Dr. Black distinguished himself in various ways. He took his degree of M.D. at Glasgow in 1820, after that he became L.R.C.S., Edinburgh, and in 1860 was admitted F.R.C.P., London. He was rather a voluminous writer, and belonged to several learned societies, in which his attainments and services were always honourably acknowledged. His life was active and devoted without intermission, until the infirmities of age compelled him to relinquish his public engagements and betake himself to a quietude befitting his declining years.

## Correspondence.

### CHEMIC ELECTRICITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In my last letter on "Chemic Electricity" (a term which I have adopted for defining more exactly its origin and *modus operandi*) I endeavoured to be as concise as possible, your space being limited; but as it seems from a letter, which has lately appeared in your journal, that my meaning has been

misconstrued, you will be kind enough, I trust, to permit me to add a few more observations on that subject.

I have adopted as my motto, that "nature alone is my guide," and, according to natural phenomena, I will now describe an electric battery of Nature's own make, which, like her other productions, will be found to be upon a grand and vast scale. (The following observations are borrowed from the work of Dr. Pallas, Medical Inspector to the French Military Hospital in Algeria):—

This natural electric battery is known by the name of volcano. Its cell consists of a subterranean cavity, containing various substances, most of them metallic. Volcanoes are near the sea-shore; and when it happens that the salt-water penetrates through a fissure, a crevice, or any other aperture, into the cavity, then oxydation takes place. (I may observe, *en passant*, that formerly we used to employ salt-water for exciting our batteries, instead of sulphuric acid, as at present.) Now, "chemic electricity" (as has been shown already) is the result of chemical decomposition, or is generated by it. Let us follow, then, the process, as it takes place. The salt-water penetrates into the hole, or cavity, which contains certain mineral substances: these oxydise, and then decompose. Heat is now evolved; incandescence increases, progressively, until ignition takes place; the substances become fused; and gases are generated. These, when they preponderate in too large quantities to be contained within, ignite, and make their escape through the aperture, which then serves them as a flue.

These are occult processes, which cannot be witnessed by the bodily eye; but which can be readily pictured to the eye of the mind.

Every kind of natural phenomenon, indeed, is the result of definite and immutable laws, and is effected upon certain conditions, which, when they meet, always give the same issue. Whether they are visible or not, things are, because they must be.

If we are asked, what is the meaning of "spontaneous combustion?" I answer, that it is produced by the causes above-named. When King Louis Philip was returning, many years ago, from paying a visit to Her Majesty, a railway building took fire. This accident caused a profound sensation at the time; for it was suspected to have been intended as an attempt upon the king's life. But the building was uninhabited. Who, do you think, was the guilty party?—It was chemic electricity. The building had been closed for a long time. It contained the refuse of greasy rags, tow, and other old materials. These fermented, were decomposed, and ignited like the flames of a volcano.

What, again, is the spontaneous combustion of the hay-rick, so common in the country?

Thrust your hand into the middle of a rick, when the weather has been showery, and the hay has been stacked before it was thoroughly dried; you will not be able to endure the heat. But, pass a current of oxygen through it, and you will see how rapidly it will blaze!

Are not these various phenomena the results of one and the same cause? Who can deny it? If, then, the same cause is existing in the human body, can we deny that it will also produce like effects, modified only, according to the constituent difference between the two bodies—the animate and inanimate. For, in the animate body, the liquids preponderate by nine-tenths over the solids, and the current of pure oxygen is also precluded—that gas existing only in given conditions, and mixed with four parts of nitrogen, in such proportions, as not to be injurious.

This statement may appear startling to those who have not followed me, or who have not studied the subject. They may also think it absurd to illustrate the functions of the body by a volcano or a haystack! I must beg leave, then, for the sake of such readers, to enlarge more on the subject than might otherwise have been necessary.

Nature is very punctilious, and very precise in her laws; nor will she brook any infringement of them with impunity. Some persons might consider this very "ridiculous" and absurd. But it matters not. No individual man, nor all the united inhabitants of the earth, will ever be able to change one iota of her laws. She governs the universe; and to seek to introduce into her government a reform bill, would be chimerical indeed.

Amongst other laws which nature has established for regulating the action of the body, is that which determines its normal degree of heat. This degree is, according to some, 98 of Fahrenheit; while Liebig places it at 99.25, a variation, however, which in no way invalidates our statement.

A mean standard of heat, then, has been established by

nature for the living body. When this standard is altered, the change, either *plus* or *minus*, becomes a cause of disease. If it is raised, the effect is hypersthenic; if it is depressed, the consequence is hyposthenic. As, therefore, the best remedies in either case are those which most readily restore the equilibrium, or the normal status of the organism, it cannot, I think, be denied that, among these, none surpass that of electricity.

I will illustrate my position with a fact.

One of my patients, a lady, had been summoned away from London upon urgent family business. When she returned to town she was labouring under the cold stage of ague, and shivered in a warm bath at a temperature of 100°. I raised the temperature to 108, and increased, at the same time, the quantity of electricity. I then made the patient pass successively through the three stages of fever, which was thus cut off at once, and did not re-appear.

Thus, my method supersedes the *chrono-thermal system* of Dr. Dickson, which, as a theory, though certainly founded upon logical principles, does not succeed in practice. The reason is this, that there is no drug which can instantaneously modify the temperature of the whole organism. I make this assertion with the greater authority, because I had, as a patient, a gentleman who was a great admirer of Dr. Dickson, and followed his treatment for five years, without being cured.

I could depend upon his statements, therefore, as he was very well informed, and a man of acute perception.

I think I have now said enough to show that the immutable laws of nature ought, on all occasions, to be the guide of the medical man, who, if I am not mistaken, should devote more time and attention to the study of natural philosophy, or, in other words, to the real book of nature, than to reading works which contain the speculations, and oftentimes the erroneous theories, of man, who, notwithstanding his lofty intellect, can never outwit nature herself.

In my last paper on Electricity I promised to treat of the second kind of natural electricity, the atmospheric; but the hints with which Mr. Thompson kindly furnished me, induced me to try to be more lucid and explicit for the future. This attempt I have now made; for, if a writer is not understood, it often happens that he is made to say what was furthest from his thoughts.

I shall beg leave, then, in conclusion, to add a few words concerning a discovery relating to electricity, but very little known.

Dr. Pacini, of Pistoia, in Italy, discovered along the nerves of a hand, which he was examining, some little whitish bodies of an elliptic shape, which had never been observed before. He thought at first that they were, perhaps, indurated molecules of the cellular tissue, and did not pay further attention at the time to the subject.

But some while after he again reverted to the matter, and determined, if possible, to ascertain what was their real character.

He found that they were connected with the adjacent nerves, and came to the conclusion that they were not integral components of the nervous system, but were anomalous formations of a pathological type. With this explanation he was satisfied for a time, but upon prosecuting his researches further he discovered that there was in the healthy and normal subject a systematic arrangement of corpuscles in the fingers, the hands, the toes, and the feet, as well as round some of the joints. He then arrived at the opinion that these little bodies were intended by some means or other to render more perfect the sense of touch. After him in 1833, Dr. Andral Camus Lacroix, having occasion to prepare some anatomical specimens for a competitive examination for the professional chair of anatomy, made the same discovery.

In 1836 Mr. Cruveilhier found out that those corpuscles do not belong to the nerves, nor to their ganglia. Some other medical men have also turned their attention to the same subject, but have not succeeded in explaining either their functions or their use. They were all agreed, however, that they were *not* nervous ganglia, inasmuch as no nervous filaments, either afferent or efferent, could be detected in them. Meanwhile, Pacini was persevering in his experiments. He dissected the corpuscles, ascertained that they had no structural connection with other organs, and that they were of a peculiar formation, which differed from all other components of the body. He found them to be elliptic cells—cells within cells—dovetailed, so to say, in with each other, while the intervening space between each was filled with a whitish transparent fluid; and ultimately he discovered that the apparatus of these bodies were of the same construction as the electric organ of the gymnotus electricus, the torpedo, and other electric fish.

M. C. Beckensteiner, a German electrician, who has devoted many years to the study of electrical phenomena, has followed up, with admirable perseverance, Pacini's discovery. After dissecting numerous corpuscles by aid of the microscope, he gave a perfect anatomical description of them, and also proved their identity with the electric organs existing in fish. This is but a cursory, and necessarily a very imperfect sketch of Beckensteiner's description, which occupies fifty-nine pages of his work. But, it will be sufficient to prove that electric apparatuses exist in all the upper classes of the animal creation. One point still remains to be cleared up. That is, the precise use and function of these corpuscles.

Dauglison, in a short notice which he gives of the "*corpuscula paciniana*" in his valuable Medical Lexicon, informs us "that their uses are not known."

In my humble opinion, these corpuscles are the *recipients*, or *reservoirs* of *chemic electricity*. They are distributed over all those parts of the system which are subject to the greatest amount of chemical action.

If at some future time you are not so pressed for space by your many contributors, I shall be happy to treat of atmospheric electricity, and the nervous ganglia. I shall then have the opportunity of again alluding to Pacini's corpuscles, and trust to be able to prove the difference between the physiological action of chemic and atmospheric electricity. The former pertaining especially to the organs concerned with the chemical action and formation of the tissues. The latter, to the nervous system, as controlling the phenomena of motion and volition.—I am, sir, faithfully yours,

J. CAPLIN, M.D.

#### COUNTY AND CITY OF CORK MEDICAL PROTECTIVE ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A memorial from this Association, of which the enclosed is a copy, was entered on the minutes of the Medical Council of Great Britain on the 29th of May last, having arrived too late for consideration in connection with the question of Medical Education. As the memorial is expected to be again before the Council at its sitting this year, may I beg the favour of you to give it the wide circulation, which a place in your Journal will secure for it.—I remain, sir, your obedient servant,  
CHARLES ARMSTRONG, Hon. Sec.

[COPY OF MEMORIAL.]

"TO THE PRESIDENT AND MEMBERS OF THE GENERAL MEDICAL COUNCIL OF THE UNITED KINGDOM.

"THE MEMORIAL OF THE COUNTY AND CITY OF CORK MEDICAL PROTECTIVE ASSOCIATION,

"RESPECTFULLY SHOWETH:—That your Memorialists look forward with deep interest to the measure which they understand is likely soon to be introduced into Parliament to amend 'The Medical Act' of 1858.

"That this Act must be looked upon as having, up to the present time, fallen short of what was expected from it, in its two principle objects, viz.:—The protection of the Public, and a really improved system of Medical Education.

"That with respect to the first of these objects, it appears to your Memorialists that Registration must continue to be all but nugatory, unless the new legislation render it imperative on the Council to order, through duly authorized officers, the prosecution of all persons incurring the penalty specified in Clause XL. of 'The Medical Act;' or that which may be substituted for it.

"That the vastly more important object of securing a sound and adequate education for all candidates for Medical and Surgical qualifications, is not, in the apprehension of your Memorialists, likely to be attained whilst the powers of the Council continue to be limited, as they are at present. To be enabled efficiently to provide for the country a body of properly qualified practitioners, it appears to Memorialists that the Council should be empowered to prescribe and enforce such educational regulations as may be found requisite for the attainment of that important object.

"That no education, Memorialists respectfully submit, can be considered sound and adequate, which does not include, as preliminary to entering on medical studies, properly so-called, such a course both literary and scientific, as will enable the student effectually to master the varied subjects of professional study with which he will have to grapple, and afterwards, to take such a position amongst men of general information, as will

be calculated to maintain for Medical Science the estimation in which it is desirable, for the good of mankind that it should be held.

"That the course for a degree in Arts in the different Universities, should, in the opinion of your Memorialists, be preliminary to that for a degree in Medicine, and that a course of education, embodying both classical studies and the various branches of Physical Science, should be indispensable before entrance on medical and surgical Education of whatsoever character.

"Wherefore, your Memorialists would respectfully suggest the expediency of the Council seeking for such a modification of Clause XLI. of 'The Medical Act,' as will secure the prosecution of offenders against its provisions. But especially of seeking for the power to establish a uniform Curriculum of Studies, preliminary and professional, which shall be binding on all the educational bodies of the country.

"And your Memorialists, &c."

#### ON THE THERAPEUTIC ACTION OF HENBANE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall occupy no more of your valuable space than to say, briefly, that if Dr. Caplin will re-read my note of March 20th, I think he will see that the dilemma in which I am placed with regard to henbane consists in this—that I am still doomed to meet with practitioners who continue to believe in the medical fables of therapeutic powers of this drug, as old, perhaps, as Paracelsus, notwithstanding all modern advances in knowledge to the contrary; and that the light I wished thrown upon it, is not that pale light of the moonbeams under which this "precious remedy" should be gathered to acquire certain fabulous properties and flourish; but the light held up by that French Commission to which I referred, for the special benefit of others.—I have the honour to be, sir, your very obedient servant,

J. CAREY, M.D., London.

## Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following were admitted Members of the College at a meeting of the Court of Examiners on the 21st inst. :—

Edward Scudamore Angove, Camborne, Cornwall; H. Schofield Baldwin, M.D., Queen's Univ. Irel., Burnley, Lancashire; Thomas Benjamin Briscoe, Calcutta; Henry Estcourt, Manchester; George Purdy Field, Sussex-gardens; Frederic Anthony Heldon, North Walsham; Christopher Haynes Jenner Hogg, Birmingham; William Leonard, Sheffield; Charles Augustus Robinson, Kingston, Jamaica; Frederick Charles Shaw, Hampstead; Henry Goldworthy Shorter, Hastings; Henry Murray Steele, Harrington-street; Frederick Henry Waylen, Haverstock-hill; Thomas Edward Webb, Aylesford, Kent; John Campbell White, Prince's-street, Westminster; William Edwin Williams, Llanhilleth, Newport; William Jones Williams, M.D. Edin., L.R.C.P. Lond., Port Madoc.

The following were admitted Members on the 22nd :—

William Bartlett Dalby, M.B. Cantab., Ashby-de-la-Zouch; Charles Goate Gordon, Boxford, Suffolk; Charles Turner Haddelsey, Caistor; John Henry Hunter, Youghal; Edward Moore Little, Melksham, Wilts; Richard Mimors, Sudbury, Derbyshire; John McKenzie, Inverness; Edward Hepburne Secomb, Clapham; Frederick Edwin Vernède, Blomfield-street, Bayswater.

It is stated that of the 34 candidates who presented themselves for examination, 8 failed to satisfy the Court as to their proficiency, and were consequently referred to their hospital studies for the period of six months. There will not be another examination for the diploma of membership until the middle of July. In the interval, Professor Hancock will commence his annual course of lectures, and will deliver six on the Anatomy and Surgery of the Foot, in continuation of those delivered last year by this gentleman. The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 14th inst., and when eligible will be admitted to the pass examination :—

Daniel George Rowlands, William Inglis Mason, Francis Day Atkins, James Cross, and William Butler, of Guy's Hospital; James Williams Danaher, Charles John Jones, Henry Worsley, and Ellis Henry Ellis, of the Dublin School; William Agar Renshaw, Handel Ashworth, and Henry Davies Crighton, of the Manchester School; George Bolton, Thomas Benson, and George Rowell, of the Newcastle School; George Harrison Evans, Richard Nightingale Broughton, and William John Noel Bell, of St. Bartholomew's Hospital; Samuel James Davidson and William Hodgson, of University College; Edmund Williams Yorath, of Charing-cross Hospital; John Rowland Wright, of St. Mary's Hospital; William Edward Baylie, of Middlesex Hospital;

Alfred John Henry Crespi, of the Birmingham School; Charles Henry Beardshaw, of the Leeds School.

The following passed on the 15th inst. :—

Charles McCann, Thomas Henry Colman, and Ferdinand Beadles, of Westminster Hospital; Ebenezer Nicholas and Charles Mead, of St. Bartholomew's Hospital; Robert Wilkinson and George Brack Johnson, of the Newcastle School; John Thos. Rodmayne, of Guy's Hospital; George Woodward, of St. George's Hospital; Henry Wotton, of Edinburgh; Matthew Lorenz Bartholomewsz, of Calcutta and Edinburgh.

It is stated that no less than 21 candidates out of the 57 who presented themselves failed to reach the collegiate standard, and were consequently referred to their studies for the period of three months.

ETHNOLOGICAL SOCIETY, LONDON.—The anniversary meeting was held on Tuesday, at the Society's Rooms, 4, St. Martin's-place, Trafalgar-square. The report of the council and treasurer was most favourable as to finances and general progress. General Balfour, in proposing a vote of thanks to the president, (Mr. Crawford), paid a well-merited compliment to his zeal and ability, on behalf of Ethnological Science, and especially his devotion of labour to the advancement of this institution in particular, which eulogium met with a warm response from the Fellows present. The Officers and Council elected for the ensuing year are:—President—John Crawford, Esq. Vice-Presidents—Robert Dunn, Esq.; Sir John Lubbock, Bt.; Professor Busk; General Balfour. Honorary Treasurer—F. Hindmarsh, Esq. Honorary Secretaries—Thomas Wright, Esq.; D. W. Nash, Esq. Honorary Librarian—L. J. Beale, Esq. Council—Lord Milton; W. Blackmore, Esq.; Henry G. Bohn, Esq.; Dr. A. Campbell; T. F. D. Croker, Esq.; Sir W. A. Clavering, Bt.; J. Dickinson, Esq.; Sir Justin Shiel; Rev. F. W. Farrar; Dr. Beddoe; Dr. Harrington Suke; Prof. Huxley; Joseph Mayer, Esq.; Sir R. I. Murchison, Bt.; Sir Charles Nicholson, Bt.; Sir Edward Rynn; C. R. des Ruffières, Esq.; Lord Strangford; John Thrupp, Esq.; Sir John Davis, Bt.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN—CANDIDATES WHO PASSED THE MAJOR EXAMINATION, MAY 22, 1867, AS PHARMACEUTICAL CHEMISTS.—Edmund Hewson Armitage, Louth; Charles Curé, Mauritius; George Thomas Naldrett, Brighton; Edward Owen, Montgomery; Lewis Buttle Ross, Driffield; James Williams, Mildenhall.

PHARMACEUTICAL CONGRESS.—Besides the Medical International Congress of Paris (August 16th) the pharmaceutical branch of the profession are to have a great meeting at Paris, to which pharmacists at home and abroad are invited. The meetings will be held on the 4th, 5th, and 6th of July next. All questions bearing upon the practice of pharmacy will be freely discussed, and it is expected that the interchange of notions and views will be conducive to the most beneficial improvements as regards theory and practice.

UNIVERSITY OF GLASGOW, DEGREES CONFERRED, MAY 16TH, 1867.—DOCTORS OF MEDICINE.—Otho Francis Wyer, William Galloway, Joseph H. Menzies, M.B.; Thomas Fielding, and William Anderson.

BACHELORS OF MEDICINE.—George A. Turner, Alexander T. Thompson, James M. Wilson, William N. Maccall, Robert Hamilton, George A. Heron, William G. Laidlaw, Archibald E. Malloch, B.A.; Eustace B. Thompson, James M'Iroy, Gavin P. Tennant, Jonathan A. Harrison, John Ewan Brodie, Duncan Crichton, James Finlayson, William Henderson, Kenneth F. McLennen, Donald Black, John M'Lauchlan, Thomas W. Jackson, Donald Fraser, Donald Campbell, Joseph Coats, William M'Laurin, John Chalmers, Frank L. Stephenson, and Henry Appleton.

MASTERS IN SURGERY.—William Henderson, George A. Turner, James M. Wilson, Alex. T. Thompson, William N. Maccall, George A. Heron, Robert Hamilton, John M'Lauchlan, Eustace B. Thompson, Jonathan A. Harrison, John Ewan Brodie, William M'Laurin, Alex. Cameron, M.D.; Frank L. Stephenson, Henry Appleton, and William Anderson.

The following gentlemen were named as entitled to Honours, to Special Commendation, and to Commendation, on account of distinguished merit at the various Examinations for the Degrees, viz. :—

I. HONOURS.—Joseph Coats, M.B.; and James Finlayson M.B.

II. SPECIAL COMMENDATION.—Gavin P. Tennant, M.B.; and Archibald E. Malloch, B.A., M.B.

III. COMMENDATION.—Henry Appleton, M.B., C.M.; John Chalmers, M.B.; and William G. Laidlaw, M.B.

**COUNTY AND CITY OF CORK MEDICO-CHIRURGICAL SOCIETY.**—At the last meeting of the Session, Wednesday evening, 8th May, the following officers were elected by ballot for the ensuing year:—President—Dr Johnston. Vice-President—Dr N. J. Hobart. Secretary—Dr Purcell. Treasurer—Dr Curtis. Council—Dr Popham; Dr Finn; Dr O'Connor. Do. three late Presidents—Dr Cummins; Dr Cremin; Dr E. R. Townsend, Jun.

**THE ENDOSCOPE.**—Professor Andrews, of Chicago, has employed the magnesium light with great advantage in the use of the endoscope for examining the urethra.—*Boston Journal*, April 11.

**THE MEDICAL TEACHERS' ASSOCIATION.**—At a meeting held on the 27th ult. the following resolutions were passed:—

"That the Association should consist of the staffs of the metropolitan hospitals and teachers in the hospital schools recognised by the examining boards.

"That the primary object of the Association should be to confer on all subjects connected with the education of medical students in the schools of London, and to be a medium of communication between the teachers.

"That the name of the Association should be The Medical Teachers' Association.

"That there should be a council of the Association, consisting of the president, with one member from each school, a treasurer, and a secretary.

"That the Association should meet at least four times in the year, one of such meetings being the annual meeting.

"That on the requisition of not less than ten members to the President, the Council should call a general meeting of the Association."

Mr. Brodhurst was elected secretary.

**RETURN of the number of promotions from the rank of Assistant-Surgeon to that of Surgeon, from the 1st day of January, 1857, to the 1st day of January, 1867, distinguishing each year separately:—**1st January to 31st December, 1857, 40; 1858, 40; 1859, 12; 1860, 12; 1861, 4; 1862, 21; 1863, 16; 1864, 25; 1865, 29; 1866, 25.—Total for 10 years, 224: average promotions per annum, 22, or 31 years' service, in all climates, previous to promotion!!—T. G. Logan, Director-General. An Assistant-Surgeon enters the service at the average age of twenty-four years, he serves, according to the above return previous to promotion, thirty-one years, making him on promotion fifty-five years, at which age he is *compulsorily* placed on the retired list on half-pay of his rank, viz. —10s. a-day.

**ROYAL ZOOLOGICAL SOCIETY OF IRELAND.**—The opening of the new monkey house, and the addition of several animals to the Society's collection, have attracted a large number of the public during the last week. More than five thousand persons visited the Gardens from the 16th to the 23rd instant, and as a very handsome pair of Condors, presented to the Society by S. R. Graves, Esq., M.P. for Liverpool, have safely arrived, an increased attendance is anticipated. These birds are the largest of the tribe of vultures, the wings usually covering a space of nine feet from tip to tip. Their powers of flight are extraordinary, and as they build their nests in the peaks of the Andes, often 15,000 feet from the level of the sea, they are seen at heights to which no human being ever reached. The Condor lives principally on carrion, but besides this mode of subsistence it will attack young goats, and a pair combining together will kill llamas, and even the Puma, an American species of tiger.

#### NOTICES TO CORRESPONDENTS.

*Dr. Martin Portlaw.*—We regret we cannot insert your letter, having declined a communication advocating the claims of another candidate. It is said that the gentleman is not a member of the Association.

*Mr. Galloway.*—The abstract is received with thanks, and shall be made use of on the earliest opportunity.

*Dr. Abraham K.*—Synonymous with A.D.

*To Dr. E.*—We believe Messrs. Walls, Close, and Co., of Cannon-street, are the manufacturers.

A Subscriber wants to know what is "Loxa Bark."—"Loxa Bark" is the old term for crown bark of commerce. Variety *Condaminia Vera*. It is found on the declivities of the mountains of Quito, in the province of Loxa (between 3°42' and 4°40' south latitude) and thus called "Loxa Bark."

*Hy. E. Browne.*—Dr. Chapman's address will be found in the "Medical Directory."

*Dr. Evanson* is thanked.

*N. F.*—You will find it in our columns of April 3.

*A Medical Student.*—Sir William Fergusson has accepted the office of President to the United Hospital Athletic Club.

A Subscriber who forwards certain corrections in our Summary of Science should bear in mind that our readers are not all proof-readers or schoolmasters, and are, we hope, content to receive information conveyed in intelligible English, without puzzling their brains in the search of printers' errors or faults of style, which, perhaps, are after all, no faults at all.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—You will be good enough to inform me what are the legal proceedings to be taken in order to stop some notorious quacks, who have taken up their residence in this part of the country. Or is there any corporation organized for the suppression of such "doctors," whose deputy it is the business of,—I am, sir, very respectfully yours,

AMICUS REI.

[We can hardly advise our correspondent to resort to the legal remedy provided by Section 40 of the Medical Act, for, owing to the frequent failure of justice, that resource has been almost abandoned. If the quack uses any title or letter, signifying that he is a member of a qualifying corporation, or that he is registered, he could then be punished, but generally assumed titles meaning nothing, such as F.R.A.S., or Member of the Royal College of Physicians and Surgeons, are adopted.—Ed. M. P. & C.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Suppose a qualified and registered Practitioner meet a quack in consultation, would the respective licensing bodies or the "Medical Council" take notice of such disreputable conduct. INQUISITOR.

[The Licensing Bodies probably, and the Medical Council certainly, would think the correction of such a practice, disreputable though it be, hardly within their province. The Council of the Royal College of Surgeons of Ireland, however, did so a few years since, and passed a resolution condemnatory of the practice, which had great effect in putting a stop to it in Dublin.—Ed. M. P. & C.]

#### MEDICAL DIARY OF THE WEEK.

THURSDAY, MAY 30.

ROYAL INSTITUTION—3 P.M., Prof. Huxley, "On Ethnology."

FRIDAY, MAY 31.

ROYAL INSTITUTION—8 P.M., J. Sterry Hunt, Esq., "On Chemistry of the Primæval World."

SATURDAY, JUNE 1.

ROYAL INSTITUTION—3 P.M., Prof. Huxley, "On Ethnology."

#### MEDICAL VACANCIES.

Birmingham Lying-in Hospital—Resident Surgeon.  
Clinical Hospital and Dispensary for Children, Manchester—House-Surgeon.

Hereford General Infirmary—Dispenser.  
Hospital for Diseases of the Chest, Victoria-park—Junior Assistant-Physician.

Jamaica Lunatic Asylum—Assistant Medical Officer.  
Nottingham County Lunatic Asylum—Assistant Medical Officer.  
Parish of Paddington—Medical Officer of Health.

#### MEDICAL APPOINTMENTS.

O'REARDON.—Daniel O'Connell O'Reardon, F.R.C.S.I., L.K. and Q.C.P.I., &c., has been appointed Medical Officer and Public Vaccinator to Kiltormer Dispensary District, Ballinasloe Union, vice Dr. Ireland, resigned.

TYRELL.—Henry J. Tyrell, Esq., F.R.C.S.I., M.R.I.A., has been appointed Surgeon to the Mater Misericordiæ Hospital in place of the late Professor Ellis.

### Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

#### BIRTHS.

CUTHBERT.—On the 27th ult., at Waterside, Derry, the wife of Alexander Cuthbert, Esq., M.D., of a daughter.

BUTLER.—On Saturday, the 25th inst., at 186 Commercial-road, Newport, Monaghan, the wife of John Butler, Esq., L.R.C.S.I., & L.R.C.P.E., of a daughter.

#### MARRIAGES.

M'WILLIAM-KIRKPATRICK.—On the 1st inst., at Ballyclare Presbyterian Church, by the Rev. Henry Cooke, D.D., LL.D., assisted by the Rev. E. Legate, William A. M'William, M.D., L.R.C.S.E., Belfast, to Mary Jane, only daughter of John Kirkpatrick, Esq., Henryfield, Ballyclare. No cards.

KEELE-LEE.—On the 14th inst., at Trinity Church, Regent's-park, C. F. Keele, M.R.C.S.E., King-street, Convent-garden, to Emma, eldest daughter of the late W. Lee, Esq., of Plymouth.

SHORLAND-BLUETT.—On the 16th inst., at Applepen, Devon, E. Shorland, M.R.C.S., of Melksham, Wilts, to Caroline, third daughter of P. F. Bluett, Esq., of South Wembury Manor, late of Holcombe Court, Devon. No cards.

#### DEATHS.

COWIE.—On the 15th inst., at Groveside Cottage, Airdrie, N.B., G. Cowie, M.D., aged 27.

DIX.—On the 10th inst., at Smallburgh, Norfolk (where he had been in practice for upwards of fifty years), John Dix, surgeon, aged 75.

HUMPAGE.—On the 16th inst., at Malvern, J. Humpage, M.R.C.S.E., of Clifton, aged 61.

LLEWELYN.—On the 15th inst., at Tunbridge Wells, J. H. Llewelyn, surgeon, 8th Hussars, aged 44.

POWELL.—On the 18th inst., at Brighton, H. Powell, M.D., Oxon, aged 68.

MEDICAL SOCIETY  
OF THE  
COLLEGE OF PHYSICIANS OF IRELAND.

The President, Professor STOKES, in the Chair.

Continuation of the Papers read before the Meeting, on  
22nd May, 1867.

(Continued from page 511.)

DR. HAVERTY, Surgeon, 52nd Light Infantry, read the following

ABSTRACT OF CASES OF CEREBRO-SPINAL MENINGITIS, AND SO CALLED BLACK TYPHUS, OR MALIGNANT PURPURA, ETC.; FROM THE HOSPITAL RECORDS OF THE 52ND LIGHT INFANTRY.

Private Hornblow—Meningitis.—On the 24th of February he was on guard at the Magazine Fort, and on being relieved next morning came to hospital with all the signs of an impending severe attack of disease. There was a tendency to prostration, with a livid purple hue of countenance, suggesting at first sight the probability of an acute affection of the lungs; but there was no cough, and no stethoscopic indication to that effect.

After lying quietly in bed for some hours, sleeping a good deal, he suddenly complained of severe pain of head, which gradually increased to such an extent that about midnight he became very restless, and when visited about four o'clock A.M., was tossing about and almost shouting with pain. The pulse at this time was firm and resisting, and between 70 and 80 beats; tongue dry and brown; skin hot and harsh; nothing peculiar in the pupils.

A few leeches to the temples; calomel and James's powder every second hour, and a turpentine enema. were followed by well-marked relief; but again in the following night, there was a recurrence of the violent head-symptoms, and on being seen at one o'clock A.M., his state was much as on the previous night. A blister was applied to the nape; the head shaved, and the tartarate of antimony ointment rubbed into the scalp.

A state of comparative quiet again succeeded for many hours, but only to be followed by the usual intense pain of head, with constant moaning and restlessness, and no steady sleep; the tongue remained dry and brown; the pulse less resisting; the pupils sluggish, but not irregular; bowels open.

On the 1st of March there was little change, except that he now for the first time complained of severe pain all along the spine, with great tenderness on pressure.

The pain of head and in the eye-balls still persistent, but not so intense as at first; tongue getting a little moist, but covered with brown fur; pupils sluggish; intestinal discharges very dark and offensive.

On the 3rd the pain of head was more troublesome than in the back; the pupils showed little or no sensibility to light, and double vision was observed. No urgent thirst was present from the beginning, and a fair amount of nourishment was taken.

Next evening there was vomiting of dark bilious matter, the irritability of stomach, hiccup, and cold sweating about the trunk lasting for some hours. The man's general conditions seemed much improved next morning, but it did not continue many hours. The usual moaning, restlessness, and sleeplessness succeeded, and he now began to refuse wine or nourishment. The bladder became inactive, the urine having to be drawn off several times in the twenty-four hours.

In the succeeding days the pain of head and back subsided to a marked degree, but the general conditions became more and more unfavourable. The tongue was again dry and glazed, pulse increased in frequency and weakness, and the thirst urgent. The wandering, which had been only occasional, was now perpetual. There was intense

restlessness and laboured respiration, and death ensued on the evening of 11th March—15 days after admission to hospital.

The treatment had consisted chiefly of the various counter-irritants already alluded to, and mercury pushed to the extent of ptyalism.

On examination of the body, there was found intense congestion of the membranes of the brain, with opaque patches of the arachnoid; the brain substance comparatively healthy. The congestion was much more intense at the base, accompanied with copious deposition of lymph, and traces of purulent matter about the pons and upper portion of the medulla oblongata. The ventricles contained a considerable amount of muddy fluid. Beneath the calvarium, near the anterior end of the longitudinal sinus; there was a patch of lymph deposit on the dura mater.

The contents of the thorax and abdomen were comparatively healthy.

Private Matthews—Meningitis.—Admitted the 16th of April with severe rigor, and the general conditions antecedent to ordinary continued fever; remaining closely covered up with the bed clothes during the day, but showing no signs of incoherency, or any remarkable or alarming symptoms until about 2 o'clock next morning, just after being at stool. At the time of going to stool he spoke in a natural manner to the orderly of the ward and for some minutes after returning to bed. Then suddenly he complained of intense pain of head, and almost immediately became insensible.

On being visited soon after by Assistant-Surgeon Gogarty, he was found insensible, as above described—the respiration laboured and very rapid, skin cold, pulse rapid and weak, pupils natural and sensible to light; no loss of sensation in the limbs, as evidenced by pinching. The stethoscope indicated very loud and clear respiratory murmur all over chest, masking the heart sounds, which were very feeble; his jaws were firmly locked, and there was incessant tossing about of arms and legs. His head was immediately shaved, cupping ordered over the nape, calomel by the mouth, and a turpentine enema.

Two hours later, when visited by myself and Dr Gogarty, all the symptoms had become much aggravated, the convulsive action was accompanied with opisthotonos, lasting for a few seconds at a time; the surface of body was quite cold, pulse weak and rapid, and barely perceptible, breathing stertorous, pupils now dilated. About the lower third of the thighs a few petechiæ were observed.

Various stimulants and counter-irritants were ineffectually tried—ammonia to the nostrils, sinapism to various parts of the body, &c.

The convulsive action ceased shortly after, except that the jaws remained locked, and death ensued in a state of comparative repose at 8.30 A.M., 23 hours after admission to hospital.

*Antopsia horis xvi., post-mortem.*—Body remarkably muscular and robust, cadaveric rigidity well marked, intense lividity (which began to appear directly after he had expired) about the head, face, and trunk; large vibices about the thighs.

On removing the calvarium, the dura mater was found adherent to a great extent in the course of the longitudinal sinus, and here and there a few pointed cheese-like eminences were seen on the surface of that membrane.

All the sinuses were distended with fluid blood, but the membranous congestion was not very remarkable, except at base of brain, where shreds of lymph were found about the pons and upper part of medulla oblongata.

In the chest no remarkable engorgement of lungs was observed, but all the great vessels were distended with fluid blood. An unusual amount of fluid was contained in the pericardium; the heart itself was large, and the right chambers distended with *post-mortem* fibrinous clots; the valves healthy.

In the abdomen the liver was found enormously enlarged, and weighed nearly six pounds; both kidneys

were enlarged and engorged, especially the left; bladder distended with fluid.

Intestines healthy.

Private Lester—Purpura maligna.—Admitted last evening, 30th April, about eight o'clock P.M., making little or no complaint, except of some pain in one leg, which afterwards extended to both limbs.

He had come off guard in the morning, and was observed to be in his usual high spirits; preparing his kit for next day's regimental inspection, &c. In the course of the day he was said to have had a rigor, but he had nothing of the kind on coming to hospital, and mentioned nothing of its having occurred.

At a late hour of the evening he was cheerful, talking to the men in the ward, and slept soundly until towards morning, when he began to ramble in his sleep, and soon after woke up complaining of severe pain in the limbs and body, but not in his head.

About seven o'clock in the morning he passed a stool under him, not unknowingly, but stated that he could not control himself. A short time previously he vomited some white frothy matter, small in quantity.

Large livid purpuric spots were now seen about the lower limbs, and signs of general prostration came on; the conjunctivæ were deeply congested, the ends of the fingers and finger-nails were livid and numb; the surface of the body, though not cold, was not warm; the tongue was thickly loaded with bright yellow deposit; the pulse was scarcely perceptible, but the heart's action, examined by the stethoscope, was not correspondingly weak; there was no approach to convulsive action as in the last case. The man replied satisfactorily to questions, though rather incoherent when left to himself. There was no pain of head throughout the case, but there was now some pain in the back of his neck, which did not extend down the spine. The prostration steadily gained ground in spite of copious stimulants and counter-irritants, and death ensued at 12.30 P.M., sixteen hours after admission to hospital.

*Post-mortem twenty-three hours after death.*—*Externally.*—Body stout and well formed, purpuric patches all over the body, more particularly over the thighs and legs.

*Head.*—Dura mater healthy; a slight increase in thickness and tenacity observable in arachnoid and pia mater; an unusual quantity of serous fluid at the base of the brain and in the spinal canal, the fluid flowing from the latter being of a much darker colour from an apparent admixture of blood. The substance of brain and of spinal chord healthy and free from congestion.

*Chest.*—Heart healthy; stained with mulberry coloured spots over its surface, and left side full of dark coloured fluid blood; one or two small dark coloured cogula in the chambers.

*Lungs.*—Healthy, congested.

*Abdomen.*—The liver pale in colour but healthy; spleen healthy; kidneys rather large, healthy; intestines healthy; bladder empty.

Private Thomas Cover—Purpura Maligna.—A healthy lad aged 19, less than two years enlisted, was observed to have a shivering fit on the morning of 6th May, and was sent to hospital by the sergeant of his company; the shivering fit ceased soon after he got to bed, slight headache and pain in the limbs were felt during the day, but nothing serious was observed in the case until about 6.30 P.M., when the countenance assumed a dusky pale ashen hue, and signs of prostration and drowsiness showed themselves, though not nearly to so intense a degree as in the late fatal cases. The eyes were free from congestion, the pulse slow and feeble, but the heart's action tolerably good, the limbs dry and tending to coldness, but no numbness or lividity of fingers. There was great unwillingness to reply to questions, but no incoherency; little or no pain of head or limbs, and no trace of convulsive action; the pupils natural.

A few livid patches now appeared on the thighs and

legs larger than petechiæ, but not so large as those of purpura. An involuntary alvine evacuation occurred about this time, a purgative enema having been given an hour or two before; vomiting occurred two or three times but was not obstinate. A cup of strong tea and afterwards port wine negus were given, sinapisms were applied over the heart, and to the limbs, and friction was used.

The stomach again rejected its contents, and after a short interval brandy and milk was given very frequently in small quantities. It was retained, and a steady reaction and improvement slowly followed. Next day well-marked reaction had become established, the pulse which had hardly numbered 70 rose to over 100, there was a good deal of general febrile action, with occasional restlessness, but no very severe pain of head; faint twitching about the angle of the mouth was observed, the tongue was slightly lateralised on protrusion, and loaded with moist whitish fur; pain was felt about the body and lower limbs, but none in the course of the spinal column; bowels not opened since yesterday; urine scanty and high coloured, and some irritability of bladder.

At midnight, on the 8th, there was great restlessness and moaning; he lay constantly on the left side with the head thrown back, and the spinal column curved to a marked degree, the face was flushed, surface of body hot and dry, and the pulse 120, double vision was also observed about this time.

His condition remained much the same during the next two or three days, but on the 11th a well-marked amendment was observed. He had several hours quiet sleep in the morning, the pulse which had been as high as 140 fell to a little over 100, the tongue was less loaded, the arched position of body much less remarkable, and the expression of eye and countenance more natural.

He continued to improve almost uninterruptedly until the 16th, when he complained of severe pain at the vertex, the left pupil was more dilated than the right, but there had been no rigor, and no marked general febrile disturbance. On the 18th there was a severe rigor about eleven o'clock A.M., following unusually severe pain of head earlier in the morning; towards evening his usual comparatively calm and comfortable condition returned, but each morning since then he has been seized with severe pain, sometimes commencing in the head, and afterwards extending to the loins and thighs, and sometimes *vice versa*. This morning, 22nd May, a prolonged shivering fit of about two hours duration occurred, ceasing about mid-day.

In the treatment of this last case, after the commencement of the reactionary fever, the administration of chlorine constituted, for a considerable time, the principal element: its employment was suggested by my friend Dr. Sinclair, who warmly advocates the views of Dr. Watson, relative to its highly valuable antiseptic properties.

#### REPORT OF FIVE CASES.

By HENRY GRAY CROLY, F.R.C.S.I.

*Case 1.*—A young gentleman, aged 16 years, previously healthy, ate heartily on Saturday, 17th March, 1866, went to Castle-yard to hear the band play, and was in high spirits; went to a dancing academy on same day, and danced every dance; passed the evening out, and drank some beer, but ate no supper.

Sunday morning, March 18th.—Looked pale, and refused breakfast; said he would not go to church, but would go to meet some friends at St. Patrick's, at three o'clock, by appointment; did not go, however; had shivering fits; went up to bed, and ate no dinner; complained at night of headache, and talked incoherently occasionally; said his throat felt sore; his stomach became irritable, which was soon followed by vomiting; conjunctivæ slightly injected; drank some tea, but vomited it almost immediately. His pulse became quick, and there was a heavy smell from him (which he noticed himself). On examining his throat it was observed to be slightly reddened. A few spots resembling purpura were remarked

on his arms, and similar spots were found to exist on the abdomen and thighs. He had no bleeding from the bowels, gums, or nose; he drank some claret; said it hurt him to swallow; throat brushed with sol. of nit. of silver.

At 12 o'clock the black spots became *broad patches*. I at once sought the advice of Professor Benson, who came with me, and advised a continuance of the claret.

I remained with the patient all night. He was restless, and raved a great deal, but slept some; drank a bottle of claret.

At eight o'clock A.M. said he felt better; drank some tea; his pulse became very rapid; temperature of body high; black spots appeared on his nose and face, and looked as if a quantity of black ink was spilled over his face; he passed no water during the night, but his bladder was not distended.

Catheter introduced. About 4oz. of natural urine drawn off. He complained now of pain in his left wrist. His pulse rose rapidly to 160; temperature of body continued high. He became suddenly insensible, and died at five o'clock (duration of illness about 30 hours).

Black spots became larger, and before death were continuous on his arms, like gangrene.

Treatment.—Brandy, beef-tea, and quinine injections; brandy, turpentine, and tr. iron by mouth.

Case 2.—J. D., a fine healthy young man, aged 22 years, residing near James's-street Harbour, by occupation a labourer; was in excellent health, ate his breakfast heartily, and went to work as usual on Saturday, July 14, 1866. At one o'clock he returned home and complained of severe headache and pain in his back; asked for a hot drink, lay in bed, and slumbered till six o'clock; took a dose of Epsom salts by the advice of a woman in the house; he vomited the medicine, and had a slight attack in his bowels; had his feet bathed, passed a most restless night, took a little punch. At seven o'clock on Sunday morning (15th inst.), black purplish spots appeared on his nose and face—similar spots appeared on his arms; at half-past eleven o'clock he died. A medical gentleman, living in the neighbourhood, was called in on Sunday morning, but the man died ere he reached the house. (Duration of illness 22½ hours.)

Case 3.—A. B., aged 19 years, a student in medicine, on Monday, April 1, took rather violent exercise. That evening he felt tired and went to bed early, but was all right the next morning. On Wednesday, 3rd inst., he was in very good health, and ate his meals very heartily. At night he complained of some soreness in his throat, but it was all gone the next morning. On Thursday, 4th inst., he got up to his breakfast and ate it as usual; none of the family saw him that morning until he returned from hospital. While at hospital he said that he had got an attack of influenza, and was altogether knocked up; he did not go up into the wards, but sat at the fire in the resident's room until after the morning visit. He got a dose of James's powder at hospital, which he brought home with him. He told several of his friends that he felt an *all-overness*. His uncle noticed a red spot in the corner of his right eye. He went to bed at two o'clock, and took some gruel, but vomited immediately after. At seven o'clock he took the James's powder. This put him into a great perspiration. He was very thirsty during the night, and drank some lemonade and water; he vomited frequently in the morning; he said he spent a very long, tiresome night, and slept very little. At about eleven o'clock last night he himself noticed some darkness on the upper lid of his right eye, and made the remark that he hoped his eye would not be injured. Friday, this morning he felt pretty well while lying down, but his head *pained* if he attempted to sit up. He took some tea, but threw it up immediately after. The lid of his eye had become much darker in colour.

Friday, April 5, eleven o'clock A.M., I saw him for the first time; he was supposed to be asleep; lying on his right side; respiration rapid; pulse rapid and feeble; coldness of hand; reddish mottling on face;

ecchymosed appearance of eyelid; on stripping patient I observed dark spots of irregular shape, some small, like ordinary purpura, and others large and of more violet hue; pupils small. I tried to get him to speak to me, but could not succeed; he soon became restless and moaned; his friends could not at first believe he was insensible, as he spoke to his aunt a few minutes before my arrival, and asked her to sit down; bladder not distended; bowels have been moved during night; he slept none; abdomen soft; vomited frequently before I saw him. I at once pronounced the case one of these called Black Death, or "Malignant Purpura" (which I consider a better name), and informed his friends of the extreme gravity of the case, and the certainty, so far as I believed, of its fatal termination.

I applied hot jars to the feet, administered brandy and ether by the mouth, but patient could only succeed in swallowing a small quantity.

I injected brandy, ether, carb. of amm. and beef-tea in small quantities and at short intervals.

He soon worked violently in convulsions, and would have fallen out of bed but for being held; upper extremities chiefly affected about half-past twelve o'clock, and head tossed about; left conjunctiva much congested; eyes half open; spots on legs and thighs larger and more irregular. He appeared to suffer much from spinal irritation, though at no time was the head actually thrown backwards. He sank rapidly, and died at half-past two o'clock. (Duration of illness 30 hours.)

The case was seen by Dr. Geoghegan about twelve o'clock, by Dr. Stokes about one, and by Dr. Benson at half-past one.

At Dr. Stokes' suggestion I added ten grs. of musk to each injection, and five drops of laudanum.

Case 4.—Anne Gill, 4 Hanbury-lane, aged 2 years, died Friday, April 26th, of ten hours' illness.

History.—Her father states the child was in good health until four o'clock on Thursday evening, the 25th instant, when she was attacked with vomiting and purging, convulsions set in about an hour and a-half before death, spots appeared (the left hand and *arm only* were convulsed)

Purplish spots appeared on her face, and some on her arms, and all over the body; the spots increased in size and number after death; none of the people in attendance ever witnessed anything like the disease, but the father took it to have been the measles.

Case 5.—Marianne Byrne, aged 21 years, always healthy and strong, resided in 48 James's-street, was attacked on Tuesday night (at half-past eight o'clock), 13th May, with severe rigors, and coldness of the surface of her body; she vomited repeatedly a slimy yellow matter, the vomiting continued until four o'clock in the morning. She had one motion from the bowels during the night.

Diarrhœa then set in, and the bowels moved at least ten times. All day, Wednesday 14th inst., she suffered from severe headache and pain in her back; blue spots, which soon became black, appeared on Wednesday on her legs; surface became colder; she died in *convulsions* with the head *forcibly thrown back at twelve o'clock on Wednesday night*. (Duration of illness 28 hours.)

Shortly before death black spots appeared on her arms. There were some on her face also.

#### REPORT OF THREE CASES WHICH OCCURRED IN MEATH HOSPITAL, UNDER THE CARE OF DRs. STOKES AND HUDSON.

Case 1.—Commencing with the ordinary symptoms of a pyrexial attack, these followed on the second day by unusual prostration, the occurrence of head symptoms, and the appearance of a peculiar eruption on the extremities.

Much muttering, delirium, stupor, and sleeplessness; gradual sicking; death on the morning of the seventh day.

Post-mortem.—Cerebral arachnitis; no apparent lesion of the spinal cord.

Mary Lewis, *æt.* 23, a servant, living in South King Street, had been in bad health for some months past. This attributable to hard work and indifferent food. Catamenia regular.

On Wednesday, January 30, 1867, she took ill, the first symptoms being a severe pain in the *right leg*. This was soon followed by headache and rigors. The same evening she had an attack of *epistaxis*. Next day there appeared on the legs and arms numerous spots somewhat resembling those of *purpura hæmorrhagica*.

She was admitted Friday evening, February 1.

Saturday Feb. 2 (fourth day of her illness).—When seen she had the appearance of just waking from a heavy drunken slumber. The face was dusky, stupid-looking, the eyes suffused and dull. The skin generally resembled that of a patient in typhus fever. She complained of great headache, principally in frontal region. Required to be roused before she answered questions; general hyperæsthesia; much muttering; delirium at times; partial retraction of the head.

Over the chest the percussion and auscultatory sounds were perfectly normal. The heart's action was occasionally irregular and very weak; there was not any murmur.

The tongue was brown, but moist; there was considerable thirst, no vomiting, appetite bad, but she took nourishment well. Bowels rather confined.

*Eruption*.—On the legs and arms were found spots of a dark purple colour, and of different sizes; all of them accurately defined and circumscribed, also slightly elevated; perfectly indelible on pressure, and in places covered with tiny papillæ, or even vesicles. The largest of these spots was about the size of a sixpence. They were confined to the extremities, with the exception of one or two small ones on the face, and many over the gluteal region.

Besides these spots there was noticed on the chest a mottling of the skin, almost passing into the form of petechiæ in places; besides a dusky hue like that of typhus.

On this morning the pulse was 84, full; the respiration 28; and the temperature 99°·6.

The treatment pursued was as follows:—

- Wine, ℥xij., oranges, chicken-broth.
- ℞ Potassæ chlorat. gr. 60.
- Sodæ bicarb. gr. 60.
- Decoct. cinchon. ℥vj.
- ℥j. cum succ. limonis ter die sumend.

Sunday, 5th day.—In much the same state—restlessness and delirium. Menstrual flow set in at night, about the regular time.

Monday, 6th day.—Pulse, 96; respiration, 63; temperature not taken. Eruption more raised, and vesicular appearance better marked; less hyperæsthesia; hardly conscious; continue treatment.

Evening.—Pulse, 116; respiration, 48; temperature, 102°·9. Sleeping, but very delirious. From this time she sank rapidly, and died calmly at 7 A.M. next morning.

*Autopsy*.—Four and a-half hours after death.—Spots unchanged in appearance. Over one spot on the *right leg* a large vesicle had formed, containing a considerable quantity of serous fluid. It will be remembered that it was in this, the *right leg*, that the pain first set in at the beginning of the patient's illness. The cuticle was not stained by the extravasation, as it was found normal in colour on raising it from off one of the spots. On the chest some brownish petechiæ were visible. The head was less retracted than during life, and there was no rigidity of the muscles of the neck.

On removing the brain, the arachnoid covering Willis' circle was found thickened and inflamed. In the sub-arachnoid spaces, and along the course of the chief vessels, small depositions of lymph were noticed. The pia mater was much congested.

The spinal cord throughout was healthy, nor was there any lesion of its membranes.

The thorax and abdomen were not examined.

*Case 2*.—Setting in with pyrexial symptoms; almost immediate prostration; delirium; hyperæsthesia; stupor; death 64 hours from first seizure.

Mary Jane Commerford, *æt.* 13, daughter to a nurse in the hospital; always enjoyed moderately good health; had not menstruated.

Took ill at 7 A.M., Wednesday, April 17th, 1867, the symptoms being shivering, headache, pains, great thirst, nausea, and frequent vomiting of a dark green substance. These were soon followed by great depression. During the day she became very restless, spoke but little, and towards evening began to wander.

Early next morning she was found delirious, and very restless, with great congestion about the face. Leeching at the mastoid process relieved her. At 9·30 A.M. she was almost unconscious, answering no question, nor taking any notice when spoken to.

The face was much congested; the eyes like those of typhus, except that the pupils were dilated; there was no noticeable strabismus; the skin was dusky; on the face were one or two small spots, many on legs and arms.

These spots were small, smooth, and *not raised*—though afterwards some became slightly elevated towards their centres.

There was no vesicular appearance, as in Case 1. Each spot had a well-defined margin; they were indelible on pressure.

When touched, she moved restlessly, but made no complaint of pain.

No physical signs were detected on examination of the chest and abdomen. The heart was very weak. There was constant vomiting of a greenish fluid, transparent, but semi-viscid. The tongue was covered with a creamy white fur. She had eaten nothing since the first attack.

Pulse, 124; resp., 44; temp., 98°·2 only.

In the evening in the same state; spots rather larger. Has had two injections of beef-tea, with quinine; also, small doses of chlorate of potash in porter, by the mouth—but this, after a short time, she refused.

Friday, third day.—More conscious this morning; can be roused by loud speaking; slept very indifferently; vomiting still continues; motions from the bowels somewhat greenish; passes water well—it is light-coloured, and on inspection seems free from anything abnormal.

Pulse, 104; resp., 24; temp., 96°·7.

Evening.—Vomiting ceased; takes some notice if roused; not so restless; if left alone falls into a heavy sleep, with loud stertorous breathing.

Pulse, 80; resp., 24; temp., 98°·6.

At 10 P.M. she rose from bed, walked about the ward, and spoke to her mother. After a short time her mind began to wander. She fancied she saw some one sitting at the fire beside her mother (who was alone). Heavy stertorous breathing came on, and without rallying she died at 11 P.M., after 64 hours' illness.

No post-mortem examination.

*Case 3*.—Beginning with head symptoms; illness attributed to fright. Much stupor. Pustular eruption on legs, red spots on arms. State improved by stimulants. Range of temperature resembling that of typhus. At present (Saturday May 11, 18th day) almost convalescent.

Mary Maguire, *æt.* 26, a nurse in Mercer's Hospital (only eleven weeks in this situation), ill since Wednesday, April 24, 1867, on which day she was much frightened by a patient who was brought in in "delirium tremens." Her head became immediately affected. She had rigors and green vomiting. Soon afterwards she fell into a drowsy state, neither speaking nor answering when spoken to. On Saturday night a rash appeared on the legs. The trunk was almost free from this. She was admitted Sunday evening, April 28.

Monday, 6th day.—In a drowsy stupid state, eyes closed; slight converging strabismus; pupils dilated. No retraction of the head; slight hyperæsthesia. No nausea; no vomiting; bowels confined; tongue (protruded towards the right side) covered with a dirty

creamy fur. Passes water at times involuntarily. Heart sounds weak, but regular; no chest signs.

*Eruption.*—Round the mouth was noticed a complete ring of herpetic vesicles. On the chest two small pustules were seen. On the legs were many of these—some of them just commencing to form, others withering and dried up. Each was surrounded by an inflammatory areola. They closely resembled the rash of varioloida. On the arms, especially near the elbows, there were seen large reddish spots, slightly elevated, and with sharply defined margins, the counterparts of the spots in case 1, except in colour, and in their being delibe on pressure.

*Treatment.*—Abundance of nourishment, stimulants in moderation, and full doses of chlorate of potash.

Tuesday, 7th day.—Pulse, 104; respiration, 30; temperature, 100°·3. More conscious; spots on legs fully out, also well-marked on arms.

Wednesday, 8th day.—Pulse, 104; respiration, 28; temperature, 100°·2.

Thursday, 9th day.—Pulse, 112; temperature, 100°·8

Friday, 10th day.—Pulse, 112; respiration, 28; temperature, 100°·3. Much better; spots fading; quite conscious.

Saturday, 11th day.—Pulse, 120; respiration, 24; temperature, 101°·7. Spots nearly gone; no pustules on legs visible; sleeps well.

Sunday, 12th day.—Pulse, 120; respiration, 24; temperature, 98°·2.

Monday, 13th day.—Pulse, 104; respiration, 24; temperature, 98°·3.

Tuesday, 14th day.—Pulse, 120; respiration, 26; temperature, 102°·4.

Wednesday, 15th day.—Pulse, 128; respiration, 30; temperature, 102°·9. Not so well; rigors; skin much mottled; pupils greatly dilated. The shiverings passed off in an hour or so, and she became much better.

Thursday, 16th day.—Pulse, 96; respiration, 22; temperature, 97°·9.

Friday, 17th day.—Pulse, 106; respiration, 24; temperature, 98°·9.

Saturday, 18th day.—Pulse, 108; respiration, 24; temperature, 98°·0.

Ordered wine,  $\bar{x}$ .

P.S.—This patient shortly afterwards left hospital quite convalescent.

The following case has great interest in connection with the complication with measles, which disease supervened in the course of the purpuric fever, and seemed to suspend it. It is given in the words of the mother of the child:—

On Friday, the 8th of last March, my little daughter Mabel, aged 6½ years, was suddenly seized with headache, shivering, and pains in the side and shoulder. She had always been a remarkably healthy child, never having had any illness, but I had observed, for some months, that she had been looking ill and pale, particularly so for a few days before her illness, and her skin had a dark shade through it, as if dirty. On this day she seemed to be quite well; spent two hours at her lessons, and ate her dinner at two o'clock with a good appetite. It was about four o'clock in the afternoon when she complained. She was put to bed, and given warm drink, and as her little brother had measles at the time, we thought she was taking them. During the night her stomach was sick six times, and each time seemed to weaken her; she also wandered a little in her sleep.

9th.—On Saturday morning, when her father saw her, he observed spots of purpura about her eyes, forehead, and chin; a leaden-coloured appearance of the entire face, particularly dark and sunken round the eyes, with an appearance of blood under the membrane at the angles of the mouth, of a lighter shade than the other spots. The dark purple spots were scattered over the back, thighs, legs, and feet; those on the lower extremities were larger and more irregular than those on the face—some of them like drops or splashes of ink—while those on the face were more like grains of shot. Her father at once ordered her as much hot

sherry and water as she could take, and mustard over the stomach, to stop the sickness, which, with headache, continued. Dr. MacDowel saw her at eleven o'clock, and prescribed stimulants and mustard-plaister to the stomach. She now complained of pain in the back of her neck, in addition to the headache and sickness. Dr. Stokes saw her at half-past three in the afternoon, and also ordered stimulants. From this hour till six o'clock she was very weak, and became very restless, throwing her head violently about, and arching her back; legs and feet cold. Her father found the heart's action very weak; pulse scarcely to be felt; he ordered immediately a strong mustard-poultice over the region of the heart, hot stupes to the legs, and gave her an enema of chicken-broth and brandy; after this she became stronger, and when Dr. MacDowel came late that night he found her flushed and feverish. The enemata were continued every three hours, sometimes adding Battley's sed. sol.

10th, Sunday.—Drs. Stokes and MacDowel saw her at 9. Observed retraction of the neck; very sick all day, and great pain in back of the neck.

11th.—On Monday morning, while Dr. Stokes was in the house, the knuckles of both hands suddenly swelled, and became of a pinkish colour, and painful. She was given Prussic acid draught, which stopped the constant sickness.

12th, Tuesday.—The purple spots were paler, but some new ones appeared on her feet and ankles, which were swollen.

13th, Wednesday.—Very feverish and sleepy, and coughed a good deal.

14th, Thursday.—Measles came out all over her; she seemed easier.

15th, Friday.—Measles still very red; during the night very restless, and on

16th, Saturday morning, several new purple spots appeared on the feet, and the measles quite faded. Dr. Stokes saw her this afternoon, the ninth day of her illness. He ordered a great deal of nourishment, wine, &c.

17th, Sunday.—Continued much the same.

18th, Monday.—Great headache; the left eye squinting. Dr. Stokes saw her. Stopped giving wine. For several days after this she lay in much the same state, very feverish, and sleeping almost constantly. Dr. MacDowel, who saw her constantly, finding very little change from day to day.

25th.—On Monday, the eighteenth day of her illness, an eruption of "Shingles" came out on her back, and increased till it was very nearly round the body, being worse on the back and chest; some of the spots very sore, and continuing so for several days.

28th, Thursday.—Great pain in the neck, and paralysis of one side of the face; the left eye staring. Iodine applied to back of neck and front of ears.

30th.—She was very restless; no sleep at night; often shrieking out as if in pain.

April 4th, Thursday.—Sickness of stomach. Very weak.

5th, Friday.—Again sick stomach. Drs. Stokes and MacDowel saw her. She slept badly, and had a continual painful kind of moan, with occasional sharp screams.

6th.—Up to this, from the beginning of her illness, she knew every one when spoken to, and answered every question quite correctly, often asking the hour, day of the week, and month, and apparently quite conscious.

8th, Monday.—She was very nervous and restless.

9th, Tuesday.—Carried on a mattress into another room quite unconscious of the movement; her stomach very sick that night, then lay so quiet that her father went over to examine her, and found her very low and weak; very weak pulse. Gave her brandy, and applied hot stupes to legs and feet, which it was almost impossible to keep warm.

10th, Wednesday.—Again sick stomach; no sleep; incessant moaning, and the eyes kept constantly twitching and squinting; the head very much thrown back; extremities cold.

11th.—On Thursday morning, the thirty-fifth day of her ill-

ness, her father shaved and blistered the top of her head, then had the whole head shaved and blistered.

Drs. Stokes and MacDowel saw her and ordered calomel. About noon she appeared relieved; the eyes better, and she was quieter; that night she was again very weak.

13th. Saturday.—Small boils came out on the back and chest; she was very restless and nervous for several days, often crying for hours, and only soothed by her sisters' singing to her.

21st.—A large abscess on the shoulder was opened; still restless and nervous.

24th.—A second abscess opened. She had several smaller ones, which gave her great pain on the head, back, and hip.

26th.—From about this day there appeared to be a very slow but gradual improvement. She was quite sensible and correct in everything she said, and knew every one, but did not remember anything of her illness.

May 8th.—She was lifted on to a small bed on castors, and was wheeled into another room, and back again at night; this has been done every day since, and she enjoys the change, but is still extremely nervous at being touched or moved.

22nd.—She remembers nothing further back than about ten days ago, which would be about the sixty-fifth day of her illness, but her memory is perfect as to everything before she was taken ill. She has now a good appetite, sleeps well at night, and enjoys her books and toys; her eyes are quite straight, also her mouth, except if she cries it is a little drawn down at one side.

I forgot to mention that during the whole of her illness, she continually complained of shooting pains in almost every part of the body, particularly in the forehead.

Dr. ATTHILL read the following:—

A. G., an infant at the breast, aged nine months, was attacked on the 14th March, with purging and vomiting, accompanied by heat of skin and great restlessness. On the evening of the same day the mother observed a red spot about one inch above the inner ankle of right leg, this was slightly elevated, and, in the course of a couple of hours, became of a dark purple colour; numerous similar spots, but of smaller size, appeared in rapid succession on both lower and upper extremities, while, at a later period, three well marked spots came out on the upper lip to the right of the mesial line. I saw the child at two o'clock P.M., on the following day (the 15th). The upper and lower extremities were then thickly covered with black spots, the majority were about the size of a split pea; some again very small, others much larger; among the latter was the one first observed on the inside of the right leg, which was as large as a fourpenny-piece; another of immense size was situated on the back of the left leg, two inches above the heel, it was oval in shape, being one and a-half inches in length, and three quarters of an inch in width. There were also some spots on the buttock, but the trunk and neck were perfectly free from them.

The child was pallid; the surface of the skin was, to the touch, apparently of the natural temperature; the eye appeared sunken, but otherwise the face did not present any remarkable appearance; he seemed, however, to be much distressed, was very restless, constantly whining and dragging at the mother's breast.

Vomiting had ceased, but the diarrhoea continued, the evacuations being pale and watery. There was not at this period the slightest symptoms of derangement of the nervous system.

Looking at the case as one of aggravated blood-poisoning, I put the child on the following mixture:—

Chloratis potasse, gr. 30  
Tinct. ferri perchloridi, ℥. 30.  
Sp. chloroformæ, ℥. 30.  
Aqueæ, ℥iv.

A teaspoonful to be given every hour. Also, with the view of checking the diarrhoea, I ordered two grains of the powder of chalk with opium, to be administered every

three hours. On the following morning, the child's condition was somewhat improved, the diarrhoea had ceased. No fresh spots had appeared, and those already in existence were unchanged in appearance. On the 17th, the general condition was much as before, but the centre of each spot now assumed that sunken silvery appearance, which has been observed in many cases of this peculiar disease. I did not in any way vary the treatment. Up to this time, there was not any symptom indicating a lesion of the nervous system, but on the 19th March, that is, on the sixth day from the first appearance of the spots, the mother remarked that the child had lost in a great degree the use of the right arm and leg. On examining the limb, I found this to be correct. The limbs were not completely paralysed, but the power of moving them was much impaired; there was also slight œdema of the right arm, with increased sensibility of the affected side, manifested by the child's crying when the affected limbs were touched, or if laid in the cradle on that side. From this period the child slowly but steadily improved. At the end of a fortnight it had regained the use of its limbs, and the spots, with the exception of the large one on the back of the left leg, had nearly disappeared. The mischief here, however, was too great to be removed by the process of absorption. Inflammation set in round its edges, and a slough, exactly similar in appearance to that caused by a superficial burn, was thrown off, leaving a large sore, which gradually healed up. The child recovered perfectly. This case was also seen by Drs. Head and Bennet.

I look on this case as one of much interest, bearing as it does on the disputed question—whether the epidemic of cerebro-spinal meningitis, and that marked by these black spots are separate diseases or different manifestations of the same poison? This case exhibited from the very commencement, in a marked manner, the black eruption, while the cerebro-spinal symptoms manifested themselves at a much later period, thus supporting, I think, the opinion that the diseases are identical.

Dr. HAYDEN read the following:—

Case 1.—Miss C., aged 19, of general good health, but subject to menorrhagia and occasional headache, was suddenly taken ill with acute pain in the head, accompanied with a feeling of tenderness all over the body, on Wednesday, October 24th, 1866. The pain having become more severe, she was visited within a few hours after her first illness by a medical man in the neighbourhood. She was then pale; skin rather cool; pulse regular and not remarkably quick; slight sickness of stomach, for which an effervescing mixture was given. In the course of that night the headache became still more urgent, and on the following morning the face was flushed, and other symptoms of high febrile action were present. Six leeches were applied behind the ears, and six grains of calomel were given at once.

I saw the patient in consultation at a quarter past one P.M., on the 27th. The face was then pale; pupils contracted, and eyes averted from the light which could not be borne. There was constant moaning and complaint of pain in the vertex and back of the head. Pulse 66, labouring and irregular. There was a murmur with the first sound of the heart, audible at the base. The head was shaved and blistered, and subsequently dressed with mercurial ointment, gr. i. of calomel was given every hour, and a warm foot-bath, containing mustard, to be frequently repeated. I saw her again at half-past seven that evening. The pulse was then 84 and full; respiration rather laboured; tongue moist; skin warm and moist; no cutaneous hyperæsthesia or sickness of stomach; bowels and kidneys acting regularly; mercurial inunction to be continued.

October 28th.—I visited the patient at ten o'clock this morning, and found her much improved, she had slept several hours in the course of the night; pulse 90, regular, and moderately full. No cardiac murmur was then to be heard; she lay with the head retracted, and avoided light;

there was partial ptosis of the right eye. A number of dark blotches resembling vibices, and not affected by pressure, had appeared upon the hands, arms, and legs, since last visit.

29th.—Diarrhœa of a biliary character, and slight pain in the head last night; the latter had ceased at the time of visit, but the skin was hot; the conjunctivæ injected; the pulse 102; and a systolic murmur was again audible at the base of the heart.

No urine had been passed since six o'clock P.M. on the preceding day; patient menstruating. The calomel was stopped, and ℞ss. of mercurial ointment was directed to be rubbed into the groins and axillæ alternately, twice a-day. A pill consisting of gr. ss. of powder of digitatis, and gr. iii. of compound squill pill was ordered to be given three times daily; simple chalk mixture to check the diarrhœa; and warm jars to be applied to the feet.

30th.—Ten A.M., patient much better; slept last night; pulse 96; skin cool; urine passed in large quantity during the night; conjunctivæ no longer injected. Finding the patient so much improved I took my leave, deeming it unnecessary to continue my attendance, and leaving her in charge of her ordinary medical adviser. On the afternoon of that day (October 30th), at six o'clock, she suddenly became alarmingly ill, "rattles" were heard in the throat, she became pulseless and cold, but continued to be conscious. Within a few minutes she was visited by the medical man in charge of her, and died in his presence shortly after his arrival, without convulsions, and apparently of syncope.

Thus, this girl's illness commenced with pain in the head, sickness of stomach, and high fever. Four days subsequently there were contraction of the pupils and photophobia, injection of the conjunctivæ, ptosis, retraction of the head, and dark ecchymosed blotches on the surface. There can be no doubt, therefore, that the cerebro-spinal symptoms preceded the cutaneous, and in this case assumed the importance of primary manifestations.

Case 2.—Miss C., aged 19, residing a short distance from Dublin, was attacked with bilious vomiting on getting out of bed on Tuesday morning, April 23rd, 1867. On the evening of that day she was seen by Dr. Monks, who found her slightly incoherent, and the entire surface of the upper and lower limbs mottled with a dark red rash, interspersed with a few unhealthy looking vesicles. A blister was applied to the nape of the neck, and gr. v. of sulphate of quinine were given every fourth hour. At seven o'clock the following morning Dr. Monks was hastily summoned to visit his patient, and found the red spots now become dark and much larger, and the patient in a state of alarming prostration. On the preceding evening he had expressed suspicions as to the nature of the affection, but he now fully diagnosed it as an example of so called "Black Death."

I saw the patient, in consultation, at ten o'clock on the morning of the 24th. She was then unconscious; pupils widely dilated and insensible to light; veins of scalp distended; loss of power of deglutition. Liquids introduced into the mouth immediately flowed out. She was remarkably restless, and struggled to get out of bed. The feet, legs, thighs, and buttocks were sparsely covered with dark spots of irregular figure, and varying in size from that of a grain of shot to a shilling-piece. These spots were in colour nearly black, slightly elevated, and not affected by pressure. Amongst these were dispersed, at long intervals, a few small undeveloped pustules.

The eruption was likewise visible on the hands, arms, and neck, and in a much less degree on the face and trunk. The general surface of the skin was of a dusky hue, and cold. Pulse 138, and weak, but regular; respiration unaltered; evacuations involuntary. The head was directed to be shaved and blistered, and then dressed with strong mercurial ointment.

Enemata of sulphuric ether and spirit of turpentine—of each ℥i., with ℞ss. of brandy in ℥ii. of strong beef-tea, to be given every second hour; the quinine to be continued, and

small quantities of brandy given by the mouth at intervals.

On the evening of that day, when seen by Dr. Monks, she was conscious; the pupils were less dilated, and fluids were swallowed readily.

On the morning of the 25th a still further improvement had taken place, but in the afternoon the patient had lost ground, and was much weaker, and at one o'clock that night, after a convulsive spasm, she died, evidently of asthenia.

It was subsequently discovered that the nurse in charge of the patient, conceiving herself entitled to have an opinion, and in the exercise of it, considering that the stimulants had disagreed with the patient, discontinued them contrary to orders after the last professional visit. To this circumstance the sudden unfavourable change in the patient's condition is probably due.

Opposite the window of the room in which this girl slept, and about eight yards distant from it, was a cow-shed, in which cattle were fattened for the market, and in the room itself the air was disagreeable and oppressive.

In estimating the diagnostic value of symptoms, it is necessary to distinguish primary or essential, from secondary or accessory phenomena; and in making this distinction, the order of succession, and the pathological relationship of the symptoms should be considered.

Judged by this rule, I feel bound to say that the cases which have come under my observation tend to support the opinion of Dr. Gordon, that the disease which has recently appeared in this country, and received the provisional designation of "Black Death," is only cerebro-spinal meningitis, with the accessory manifestation of cutaneous ecchymoses and eruption. I grant that there is great difficulty in explaining the genetic connection between the pathological and vital conditions indicated by these two groups of symptoms—namely, an inflammatory organic lesion of the cerebro-spinal meninges, and deterioration of the blood.

Short notes of two cases, under the care of Mr. DARBY, of Bray:—

Case 1.—Margaret Brady, aged 15 years, admitted to the Rathdown Hospital, at two o'clock, P.M., 22nd March, 1867, reported as having been in perfect health up to the evening of 19th inst., when she was suddenly attacked by a rigor, followed by a convulsive fit, after which she totally lost her hearing, complained of headache, and vomited.

On admission her skin was hot; pulse quick; tongue clean, but fringed with aphthous ulcers, as if the edges had been bitten; her eyes were bright, watchful, and wild, pupils medium size, acted slowly under the influence of strong light; her head drawn sharply back upon the neck; was constantly muttering, moaning, and grinding her teeth. She cried out whenever any part of the surface of her body or limbs was touched. Spots of a dark colour, nearly black, of varied form and size, were found on the fore-arms and legs, resembling, for the most part, the marks of an itch or other papular eruption that had recently died away. There was also an ecchymosed patch on the right thigh. For two days after admission fresh spots continued to appear, and some of the old ones began to fade to a greenish-yellow, and some to disappear altogether.

On the 27th all the spots were fading.

On the 1st April there was not a trace of any eruption or discolouration on the skin; other symptoms continued without any marked alteration. The girl wasted, sunk gradually, and died of exhaustion on 23rd April, 1867.

The post-mortem revealed lymph on the surface of the pons varolii and medulla oblongata; about four ounces serous fluid in the ventricles extended into the spinal canal. The membranes of the cord were much congested.

Case 2.—Thomas Carroll, aged 10 years, was admitted to hospital, from the workhouse school, on the 11th April, 1867. Reported not to have eaten his food well on the previous day, and spat up a little blood; on rising from bed this morning some red (blood) spots were observed on his skin, he spat up more blood, and was consequently

sent to hospital. I found him at noon lying quietly in bed, not complaining; his pulse was 90; tongue furred; gums bleeding; skin cool. Face, limbs, and trunk were thickly dotted with black spots, elevated slightly, and varying in size from a grain of shot to that of a pea. Two ecchymosed patches—one the size of a shilling, the other as large as a penny-piece—were observed on his legs; his belly tumid. Ordered an oil and turpentine draught, immediately, which produced a copious, tar-like stool, free from smell. Lemon juice was freely given, and ten drop doses of spirits of turpentine every fourth hour. This treatment, with nourishing diet, was continued up to 22nd (11 days), when he was discharged cured.

I have thought that some analogy existed between these two cases, as some of the spots on the skin in either case bore a strong resemblance to the other—the local inflammation in the case of Brady being altogether absent in Carroll, forms the chief feature of difference between them, and as that is a point in the prevailing epidemic disease upon which a difference of opinion exists in the profession, I place the cases in juxtaposition.

The following letter was read from Dr. Crooke, of Macroom:—

“May 6th, 1867.

“DEAR DR. BELCHER,—I have read with great interest your case in THE MEDICAL PRESS AND CIRCULAR of May 1st.

I entertain no doubt that it was a case of fever. I have attended in the Fever Hospital here, during the past twelve months, six cases closely resembling it in most of the details. I may state that I treat in this hospital an average number of about twenty throughout the year; they are chiefly household servants, male and female, sent in from a wide area of country. They are usually well fed and nourished. If a change is made in Cullen's aphorism: “Initio febris gastricus, progressu et versus finem typhus,” it will describe this form of fever. The first case of this class which I treated last year occurred in the month of February, and bore a resemblance to yours, so remarkable that I will give you an extract from my notes of it:—S. W., aged 20, nursery governess to Lady —, a tall fair German, of considerable personal attractions, and of nervous temperament. Her illness, as in your case, was caused by exposure to cold. During the first ten days she suffered from gastric fever with bilious vomiting; pulse not above 90; there was considerable prostration of strength, slight headache, and heavy pains in the back and thighs; excessive sleeplessness; thirst; tongue red at the edges, foul occasionally in the centre, and generally moist. At the end of ten days there was a complete remission for thirty-six hours, and I thought she was going to get well, but a different train of symptoms followed. Sleeplessness returned, and with it delirium appeared for the first time, then followed jactitation of the limbs, picking of the bed-clothes, tympanitis, involuntary evacuations, coma, and death ensued on the eight day of the second stage. The duration of her illness was thus eighteen days, about the same as in your case. On the day following her death her countenance became of a livid, almost purple colour; her stomach became enormously distended on the next day; her face was almost quite black; there was a putrid odour in the room, and, as it was evident that decomposition was advancing rapidly, I had her removed to her grave without further delay. I have notes of five other cases treated during the past year, two males and three females—all were young, ages 16, 19, 20, 20, 22 years. The gastric stage varied in duration from seven to ten days; the typhoid stage from nine to fifteen days—all recovered. In each of these five cases the attacks were distinctly traceable to contagion, pure typhus having existed in each house from which they were brought. In three of these cases an abundant eruption of petechiæ occurred when the typhoid symptoms occurred. Do you not think that the disease, termed by Dr. Mayne and others ‘cerebro-spinal arachnitis,’ is a specific fever of a malignant character, and that the inflammation of the mem-

branes which invest the brain and spinal marrow, is one of the effects of a poisoned and morbid condition of the blood, and not the essence of the disease? There is nothing new in specific fever terminating fatally within twenty-four hours; when malignant scarlatina prevailed it was not uncommon to meet cases which succumbed to the disease within this period. I witnessed at least twelve such, and heard of many others. The leading symptoms were bilious vomiting, low delirium, rapid prostration, coma, and death. The term “Black Death” may well have been applied to some of these cases; for, within twenty-four hours after dissolution, the countenance assumed a dark purple hue, and decomposition set in so rapidly that the remains had to be hurried from the view of the horror-struck relatives. I shall never forget one dreadful instance of this kind which happened in my neighbourhood, when a most promising young man of 19, was carried off by this dire disease in about eighteen hours from its first invasion. I am no believer in this new ‘sensation tale,’ that the ‘Black Death’ of the ‘middle ages’ has reappeared. . . . I am, sir, yours, &c., WARREN CROOKE.”

Conclusion of Meeting held on the 22nd of May. In our next issue will appear the discussion which took place on the 24th of May.

MEETING OF THE  
GENERAL MEDICAL COUNCIL  
OF EDUCATION AND REGISTRATION.

SESSION 1867.

WEDNESDAY, 29th MAY.

The President, Dr. BURROWS, in the Chair.

PRESENT—Mr. Cæsar Hawkins, Mr. Cooper, Dr. Acland, Dr. Paget, Dr. Embleton, Dr. Storrar, Dr. Alexander Wood, Dr. Andrew Wood, Dr. Fleming, Mr. Syme, Dr. Allen Thomson, Dr. Aquilla Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Sir D. J. Corrigan, Bart., Dr. Sharpey, Dr. Parkes, Dr. Quain, Mr. Rumsey, Dr. Christison, Dr. Stokes, and Dr. Francis Hawkins, Registrar. The roll having been called,

Dr. RISDON BENNETT, the newly elected representative of the Royal College of Physicians, was introduced by Dr. Paget, and took his seat in the Council.

The President then delivered his inaugural address as follows:—

Gentlemen—Before we resume our accustomed labours at this Council table—labours which have been so often devoted to the improvement of the social and scientific position of the great commonwealth of the medical profession throughout the British empire—I will crave permission to offer you a few introductory remarks before we proceed to the regular business of the session. Your deliberations upon several subjects of importance, subjects which have anxiously and largely occupied your attention in former years, were terminated during the last session, and your conclusions were embodied in certain reports and recommendations which were printed and circulated throughout the country. To my mind, one of the most important topics which engaged your attention last year was the report of your Committee upon General Education, that is to say, the report upon the subjects which were to constitute the preliminary examination of students in general education. Of all the labours which have been bestowed by this Council upon various subjects, I am of opinion that none is likely to be more productive of benefits, present and prospective, to the whole profession individually and collectively, than the establishment of a compulsory examination in subjects of general education, for all persons, before they are permitted to enter the medical profession. If the medical practitioner is still to maintain his proper position and influence among the educated classes of society; if our profession as a whole is still to bear the name and be regarded as one of the

learned professions, then undoubtedly those who enter upon it ought to have received that amount of mental culture which would render them capable of passing a preliminary examination in subjects of general education, which should be equivalent at any rate to the examinations passed by those who are entering upon the clerical profession, the legal profession, the army or the civil service of the country. Unfortunately, the Medical Act under which we are assembled here, and by whose provisions we are regulated, did not give us as a Council any power to encourage or to distinguish individuals of high literary attainments, or of great professional knowledge; but that Act of Parliament has given us power to establish a standard of education below which we can say that no man is fitted to enter our profession; and I do trust, therefore, that the Council will agree among themselves to keep up the standard to as high a point as the circumstances of the case will permit. It is true, indeed, that this Council cannot assume to itself the credit of having initiated these examinations in general education of students about to enter the medical profession, because of course the great universities of the land and many other corporate bodies had instituted examinations of this kind prior even to the formation of this Council. But then these examinations in general education were not preliminary examinations. They were by no means uniform; they were passed at most irregular times, while the student was, or at any rate ought to have been, engaged in professional studies, and even sometimes just prior to the final qualifying professional examination of the individual. Now, it must be obvious to all that examinations in general education, conducted at such irregular and at such unsuitable times, could not attain the object which this Council had in view, and could afford us no kind of security that students had been sufficiently instructed in subjects of general education before they were permitted to enter upon the curriculum of professional study. During the last session, gentlemen, we arranged and circulated in a convenient form our code of regulations and recommendations—as far, indeed, as they had been completed and perfected upon several points—first upon the subject of preliminary examination of students in general education; and also upon the important subject of the mode of the registration of medical students; thirdly, upon the curriculum of professional education; fourthly, upon the successive professional examinations; and fifthly, upon the supervision of all examinations held by the qualifying bodies. I say we circulated these recommendations in a convenient form as far as they were then perfected. No doubt there are many that yet demand a far greater improvement. In respect to the last-mentioned of these regulations—that is to say the supervision of examinations—you happily persisted in your former resolution, that the visitation of examinations should be continued as before; but, in your last session, you also went further, and passed an important resolution, the words of which I have here before me. You resolved, that the visitation of examinations should be continued as before, and you further determined that the reports of the visitors should apply to every part of those examinations, and should include a statement of the facts observed, and of the opinions of the visitors as to the efficiency of the examinations, as also remarks and suggestions upon any defects perceived in them. Now, I honestly believe that if any impartial person would take the trouble to peruse these reports of the visitors of examinations for the last two years—I wish I could say peruse the reports of all the examinations, for there are one or two certainly very pitiable exceptions—he would find there not only grounds for the necessity which exists for the supervision of these examinations, but he would also find unequivocal proofs of the benefits already obtained by the plan which has been hitherto pursued. I would not wish you, gentlemen, or the public out of doors who may become acquainted with what I am now stating, to suppose that I am so far an optimist in regard to what is done by this Council as to assert either that the supervision of examinations has been conducted upon a system,

or by persons whom theoretically I should conceive the best adapted for the purpose.\* The supervision of the examinations, however, which are carried on by universities and colleges of great antiquity and repute, must necessarily be, to a certain extent, an invidious task, and it is a duty requiring to be performed with great tact, prudence, and forbearance. A more rigid, uniform, systematic plan for carrying on these examinations, might, in the first instance, I fear, have met with more opposition, have given rise to heartburnings, and have afforded far less satisfactory results than have been obtained by the cautious, tentative, and more imperfect system which we have hitherto adopted. In the first series of reports of visitors of examinations, we find various remarks and suggestions which have not only been taken in good part by the qualifying bodies—and those of the very highest standing and character—but they have been acted upon by several examining bodies without delay; and you will find, in the reports of the visitors of examinations of this year, the fruits of suggestions made in the reports of the preceding year. Gentlemen, I think there is great cause for congratulation that you should have commenced and carried on this system of supervision of examinations, without more seriously hurting the susceptibilities of the honourable and distinguished men who are engaged in conducting these examinations; and the results which we have already obtained give us an earnest of great improvement in the method of ascertaining the fitness of candidates to enter upon the varied duties of their profession. Let me here pause for one moment, and just take a brief review of what this Council is doing, and has so far effected, to insure throughout the United Kingdom that the medical practitioner should be better fitted for his social station, and also more equal to the emergencies of his responsible calling. If this Council persist in enforcing a good preliminary examination in subjects of general education upon all persons who are about to enter the medical profession, and before they are allowed to register themselves as medical students; if the curriculum of medical study be established, and be sufficiently long to enable persons of ordinary ability to acquire a sound knowledge in various branches of medical and surgical science; and if the professional examinations are conducted at regular stages and proper intervals during the curriculum; and if this Council can be assured, through their visitors, that these examinations are really efficiently and impartially conducted—then I say that the Medical Council have done their duty in this matter of education, to the profession and the public, and they may bid defiance to their detractors out of doors—and we have those who have endeavoured to detract from our credit—who carp at, and are jealous of the authority of this central controlling body, and who are, therefore, desirous of impairing the prestige and influence of the General Medical Council. Among the arduous tasks assigned by the Legislature to this Council, as representing the interests and wants of the whole medical profession of the United Kingdom, none was beset with more inevitable difficulties than the preparation of the Pharmacopœia which should supersede the Pharmacopœias of the College of Physicians of London, of Edinburgh, and of Dublin. The reduction of the Pharmacopœias of the several colleges into one work for general use throughout the United Kingdom, had become a great want, an absolute necessity, and although this object had been previously attempted more than once, the attempt had failed. The British Pharmacopœia of 1864, a work of great labour and merit, had indeed accomplished this object, and was a manifest proof that this Council had the will and the ability to cope with, and overcome, difficulties which had previously proved insuperable. Although the Pharmacopœia was not so favourably received as we should have desired, still, considering that on its appearance the work was, to a certain extent, an intruder everywhere—perhaps a *parvenu*—superseding the old established Pharmacopœias of the several divisions of the United Kingdom, we ought not to be surprised that it

met with a rather cold reception. Gentlemen, the Committee entrusted by this Council with the preparation of a new edition of the British Pharmacopœia having completed the duties assigned to them, and it is impossible to mention this subject without recording how deeply the Pharmacopœia Committee were indebted to their indefatigable Honorary Secretary (Dr. Quain), without whose energy, tact, and perseverance, I firmly believe the labours of that Committee would hardly yet have been concluded. However, the Executive Committee have published the work in accordance with the resolutions of this Council. I can hardly suppose that any work of a similar kind ever had more patient labour bestowed upon its preparation by its editors than this Pharmacopœia—and I must here mention the labours of Professor Redwood, and how ready he was upon all occasions, as far as his judgment would permit, to accede to the wishes expressed by members of this Council; neither can I suppose that any work ever received a more careful and searching revision both by the scientific and accomplished members of this Council, as well as by skillful pharmacutists to whom the work was submitted who were not members of this Council. As far, therefore, as an opinion can be formed from the remarks and criticisms of public journals, we may anticipate a most favourable reception to this edition of the British Pharmacopœia, and that it will prove a most favourable standard work for general use for the profession throughout the empire. Gentlemen, it was only yesterday that your Executive Committee determined that the official announcement of the publication of the Pharmacopœia should be made in the *Gazettes* of London, Dublin, and Edinburgh, and that after a certain day our new edition of the British Pharmacopœia will be the only recognized Pharmacopœia; and it is very much to be hoped that after that period all loyal men, whether physicians or surgeons, will employ the new edition to the exclusion of all former Pharmacopœias. Unless this course is generally adopted, we cannot expect the Pharmacopœia to accomplish the great good that it is capable of effecting. Gentlemen, the last topic to which I will allude is the course of the negotiations of the Executive Committee and your President with the Government upon the Medical Acts' Amendment Bill. It will be in your recollection that towards the close of your session of last year you came to a resolution that a letter should be written to the then Home Secretary, Sir George Grey, and that this letter should be accompanied with a draft of the Medical Amendment Acts Bill as approved by this Council, and also with a statement of the reasons why this Council thought it right to deviate in certain particulars from the draft of the Bill we had received from the Home Office. In the concluding paragraph of that letter it is stated: "And I may ask that you will at your earliest convenience be pleased to receive a deputation from the Council to consider the Amendment in question." Now you are aware that shortly after that period the Government resigned, and Sir George Grey necessarily went out of office, therefore the President and the Executive Committee had no opportunity of seeking that interview with Sir George Grey. However, you will recollect that at a subsequent meeting of the Medical Council on May 29th, 1866, you passed a resolution in the following words: "That it be delegated to the Executive Committee to confer with the Government regarding the proposed Bill—the Amendment to the Medical Acts, and to press on the Government the expediency of its being adopted as a Government measure, and at the same time to state that the Medical Council are of opinion that unless the Bill be introduced by the Government it would be unadvisable to proceed with it." Now, in accordance with that resolution, at the first meeting of the Executive Committee following your separation last year—17th of July—the Executive Committee determined, as deputation, to wait upon the new Secretary of State, Mr. Walpole, and your President, accompanied by Dr. Andrew Wood and Dr. Aquila Smith, and the Registrar, waited

upon Mr. Walpole, who received us kindly and courteously, and listened to all we had to say with great attention. We endeavoured to put before him the feelings and wishes of the Council, and the absolute necessity there was of an amendment of the original Act of 1858. Indeed, Mr. Walpole himself seemed to be conscious of the defects of that Act, and he led us at that time to hope, without any definite promise, that he would take up the subject at a later period, and he also intimated that he would be happy in the ensuing autumn to see your President, and to go into the matter with him. Therefore, when the autumn had arrived, in the month of November, in accordance with the wish so expressed by him, I put myself in communication with Mr. Secretary Walpole, both by letter and by a personal conference, and endeavoured, as far as I could, to reiterate all the statements and arguments used by the deputation of the Executive Committee in July, 1866. In consequence of some delay in getting any reply to this communication, I had occasion to write to that gentleman more than once, but on the 2nd of February of this year, Mr. Walpole wrote a letter, stating that, although he was aware of the necessity for an amendment to the Bill, he felt himself so burdened with the various other bills which the Government had on hand, that he could not then promise to undertake it, and he suggested that we should endeavour to obtain the assistance of some private member, either in the House of Commons or House of Lords, who would take up the Bill. But as that was not in accordance with the expressed wish and resolution of the Council, of course it could not be acted upon, and I intimated to Mr. Walpole that such was your determination last year. The thing then remained to a certain extent in abeyance, and I thought it better to press Mr. Walpole for another interview, which was granted to me on March the 11th. I then again brought the whole subject before him, and upon that occasion I met the legal adviser of the Home Office. I endeavoured to impress upon Mr. Walpole what the Profession and this Council expected from him, more especially as he had himself introduced the original Bill into Parliament. He promised that I should hear from him shortly what he had decided upon. However, that communication was so long delayed, that it was absolutely necessary again to remind him of the necessity of learning his final decision before the Council met, and it was only last week, since you received your summons to attend at this board, and since the programme of business was issued, that I have received from him a very important communication suggesting modifications in one of the clauses of the Medical Act's Amendment Bill, agreed upon by Council last year. That is a matter of such importance that I will not enter into it now, but merely mention that I hope you will, in accordance with the recommendation of the Executive Committee, think it sufficiently urgent to take it into consideration at an early hour of this day's proceedings. I have thus, gentlemen, endeavoured succinctly to give you a sketch of all that has transpired here since we separated last year. There still remains, of course, many questions of great interest to be discussed and settled at this meeting, although I believe that some of the greatest difficulties that surrounded your onward progress have now been surmounted. The profession out of doors looks to you as a body to sustain its place in the social circle, and to obtain, if possible, from the legislature better means of preventing the quack and impostor from personating the regularly educated practitioner. Gentlemen, I trust we shall enter upon our discussions this year with all that calmness which befits our station, and endeavour, as far as possible, to make our observations with brevity of diction, which will shorten our labour, and with courtesy of manner and avoidance of personality, however much we may differ in sentiment, feeling assured that the opinions of men who sit around the council-table are not likely to be swayed by any charms of rhetoric, nor their cool and mature judgments biased by any violence of language. Gentlemen, I now conclude, and you will please to proceed to business.

A communication from the Home Secretary was laid before the Council containing the following passage:—

"I must remind you that the difficulties which have arisen in respect of this Bill are in no degree chargeable to the Home Office, but they arise from the fact that the Medical Council had deviated from the form of Clause 11, as settled last year by that office. Should the Medical Council be willing to adopt in place of Clause 11 the amended clause that accompanies this letter, I do not think that the Government would offer any opposition to the Bill; but as the Bill is not a Government Bill I must express my concurrence with the opinion expressed by Sir George Grey, contained in Mr. Murdock's letter of the 11th of May, 1866, that it would be well for the Medical Council to entrust the Bill to some independent member."

PROPOSED CLAUSE.

"Every person who has resided in the United Kingdom for a period of not less than twelve months immediately previous to making his application, and who legally possesses a colonial or foreign degree, licence, or other diploma, from a university, college, or other body which qualifies him to practise medicine or surgery in the colony or foreign country where such degree, licence, or other diploma was obtained, shall be entitled to be registered under the Medical Act, 1858. Provided such degree, licence, or other diploma shall have been granted by a university, college, or other body which in the opinion of the Medical Council or one of her Majesty's principal Secretaries of State, grants decrees, licences, and diplomas after such course of study and examination as guarantees the possession by the holder of sufficient knowledge and skill for the efficient practice of medicine and surgery."

The clause as originally proposed by the Home Office, and that adopted by the Council last year, were then read.

Dr. PAGET—I beg to propose that a committee be appointed to take this subject into consideration. It appears to me that Mr. Walpole's communication entirely puts an end to the small hopes that were still left to us of carrying through any Medical Acts Amendment Bill in the present session. Considering how completely the House of Commons is at present and will be engaged with the English, Scotch, and Irish Reform Bills, it seems to me utterly impossible that any measure can be effectually introduced this session, even under the favourable circumstances of its receiving the support of the Government. But if I understand Mr. Walpole's communication, it amounts to this, that the Government only promises that it will abstain from active opposition to the measure. I think our best plan will be to refer the whole matter to a committee to consider what is best to be done under the circumstances, and to report to the Council as speedily as possible. I think this is the more advisable, because, speaking for myself, I think there are serious objections to the condition that Mr. Walpole has annexed to the consent of the Government, the admission of this clause with reference to the registration of persons holding foreign and colonial diplomas. I am well aware that the Council individually and collectively have the best possible feeling towards the holders of foreign and colonial diplomas, whether Englishmen or foreigners; and no doubt there are many instances of persons distinguished in science, like Dr. Séguard and others, whom the Council would willingly place on the register without requiring from them any diploma or licence from English qualifying bodies. But Mr. Walpole's proposition, which agrees in the main with that of Sir George Grey, is not that individuals, but that certain universities and colleges should be recognised, and that any person holding their diploma should be entitled to be registered. It does, no doubt, propose that the Council should have the power of naming the universities; but it also gives the same power to one of the Secretaries of State. So that it might happen that the Council might be compelled to register the holder of a diploma from some homeopathic or other college favoured by a Secretary of State, although they might consider him wholly unfit to appear as a

British practitioner. Now, I think that is exceedingly objectionable, and almost as great an absurdity as the granting of medical degrees by the Archbishop of Canterbury. If this matter were a mere question affecting the interests of the qualifying bodies, I do not think the Council would allow it to weigh against what seems reasonable and fair. If it were possible to put the foreign and colonial universities and colleges on an equality with the English, I feel sure the Council would do it, but it is not possible—at least, I do not see how it can be done. The Council is invested with certain authority in regard to the British diplomating bodies—that of inquiring into the course of study, visiting the examinations, representing to the Privy Council, and suspending the power of granting licences, which it does not possess and could not exercise with regard to foreign and colonial bodies. Those powers are of the utmost importance with reference to the functions of the Council; and by their exercise the Council have established a minimum of qualifications for practitioners, both in general and professional knowledge, by means of which they hope to elevate the social status of the profession, so that the most ignorant practitioner in the country may be a decently well-informed man. Let me remind the Council of the manner in which this clause might work. We might have a Foreign Secretary who felt an interest in some country with which we were in alliance, or upon "touching" terms; or a Colonial Secretary, interested in some colony that was beginning to quarrel with us. I think our present course is to appoint a committee.

Mr. RUMSEY—Although nominated by the Crown to the seat I have the honour to hold at this Council, I cannot avoid on the present occasion expressing my deep surprise and regret at the manner in which the Government of this country has received the communication made by the Council through you, sir, after our last session. I do not wish to say more than is absolutely necessary, but I do conceive that the Council, which has been called into being by the Legislature of the country, and placed in relation with one of the highest departments of the State—the Privy Council—had at least some claim upon the Government to be regarded as an authority in the matter of the Medical Acts Amendment Bill; that the Government should certainly, if they did not approve of the provisions of the Bill, or any one of them, have given reasons for such disapproval. As far as I understand the communication which has been made to us to-day, the Government have not condescended to give the slightest reason for the alteration they have made in the clause of last year. The Report of the Committee on the Draft Bill last year gave most ample reasons for the proposed change; and it would have been only courteous, to say the least, in the Government to give an answer to that Report.

Mr. CÆSAR HAWKINS seconded the motion of Dr. Paget.

Mr. SYME said that he thought the subject required a more speedy expression of the Council's opinion than that proposed by Dr. Paget's motion. He agreed with Mr. Rumsey that the Council had great reason to complain of the Government for their indifference and apathy; but they had now gone beyond indifference, and had actually insulted the Council. (Hear, hear.) They had taken upon themselves duties which Parliament had delegated to the Medical Council as among its principal functions. It was not a mere matter of etiquette; but it was a proposal the adoption of which would render the Council and its actions utterly ridiculous. Who could doubt that some Secretary of State would be disposed, through private friendship or representations of various kinds, to nominate some person who would be a disgrace to the body? Instead of appointing a Committee, he proposed that a communication should be addressed to Mr. Walpole, to the effect that the Medical Council could never entertain such a proposition. We could then communicate with his successor; and I have reason to believe that that communication would be of a very different kind.

[For continuation, see page 539.]

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 5, 1867.

### UNIVERSITY REPRESENTATION.

WE have several times insisted on the rights of the unrepresented Universities of the United Kingdom to be admitted to the privilege of sending members to Parliament. The Universities that have long exercised this privilege have always been most influential constituencies, and the members returned by them worthy of their electors. This is not a question of party. Learned bodies of this description are eminently calculated to leaven the wider electoral districts of boroughs and counties, and secure for the more highly educated classes, as such, a voice in the affairs of the nation they may not otherwise acquire, but certainly ought to possess. Yet, the creation of University constituencies cannot set class against class. Medicine, Law, the Church, the Arts and Sciences—all have their votaries amongst the graduates, to say nothing of the large numbers of what may be called the purely educated, in contradistinction to the strictly professional element. If Medicine in some Universities be in the ascendant, it would in this manner obtain only indirect representation; and should the movement lead to half-a-dozen Medical Graduates taking their seats in the House of Commons, we think the country might well be congratulated on the result.

The many questions that come before the Legislature on which Medical opinion ought to be expressed are well-known to our readers, and we believe the public would be glad to see the Profession lending its aid on these occasions. Had the Body Medical always been adequately represented in Parliament, half the social reforms for which we now cry would have been long since effected. Probably, an efficient Department of Public Health would have conferred inestimable benefits on the community, and the scandals that have disgraced our Poor-law administration would have been avoided. No class of men so thoroughly devotes itself to doing good as the Medical Profession, and a large majority of the agitations for social reforms originate in its ranks. At the present moment, the Vaccination Bill is a proof of the necessity for a race of Medical Statesmen. Yet it is not as a class that we just now advocate our claims to a share in the Government. If we do not possess sufficient interest in the Universities to secure some of the seats, we must wait until a larger number of practitioners become graduates.

In the University of London, a preliminary movement to secure the return of a Medical Graduate has already commenced, and when we look at the

calendar, and see the great preponderance of the medical element, we feel that success is certain. And so of the Scotch Universities. At least, one of the two members proposed to be bestowed on these bodies ought to be a medical man. We have no sympathy whatever with the notion that a non-graduate ought to be allowed to represent any University. Every one of these bodies possesses ample choice in its own ranks, and the idea of going beyond should be at once repudiated.

Respecting the concession that has been made, the Government can lay claim to no great *liberality*. The injustice of the Metropolitan University only having one member, while Oxford, Cambridge, and Dublin have two each, has already been pointed out in our columns, and the offer of two members between the four Scotch universities is equally niggardly. Still, on the principle that "half a loaf is better than no bread," we may accept this instalment from the hands of our very *Conservative* remodellers of the Constitution.

In the Scotch Reform Bill, which has been printed for the use of members, this very moderate concession to the Universities is to be guarded by a series of restrictions infinitely more unfair than those that were proposed in other cases, but relinquished on "gentle pressure." As the Bill now stands, only those are to have a vote who belong to the General Councils of the Universities, and have attended certain classes. Nothing could be more unjust, and the whole body of graduates must of necessity protest against the iniquity. We want no close boroughs—no petty monopolies. Every Graduate of a University ought, as a matter of course, to possess the franchise, and to exercise it by means of voting papers. Otherwise only discord will ensue. There is not the shadow of a pretence for the proposed restrictions, and unless they are at once withdrawn we hope every Graduate in the kingdom will bring all his influence to bear on Members of Parliament with a view to defeat the most unjustifiable restrictions ever devised by the most thoroughly Tory politician. One instance of the iniquitous manner in which these restrictions will act may suffice. One of them would deprive of the franchise the Medical Graduates of St. Andrews, who obtained their degrees before the New Constitution was conferred on their University—that is, before 1863. This would absolutely exclude those who graduated during the whole time that Dr. Day was the Professor of Medicine—notoriously a time in which the examinations were peculiarly thorough and searching. It is well-known that Dr. Day did much to raise the standard of the University, which, under his auspices, greatly increased its renown, and St. Andrews' men, who obtained their degrees during that period, are wont to boast of the distinction of

being "Day's Graduates." And yet, forsooth, these men are to be deprived of the franchise to gratify Tory partiality for restrictions, or to enable the *Conservatives*, under the banner of Reform, to create close boroughs, more dangerous to the community than Old Sarum itself. Never was a more transparent trick attempted to be palmed off, nor a greater insult offered to such a class of men. Better no University representation at all than such a sham as this.

We rejoice to find that the St. Andrews' Graduates, alive to the injustice proposed to be inflicted upon them are already at work.\* The St. Andrews' Graduates' Association, which on a former occasion did good service, has been resuscitated, and the most active steps are being taken to bring under the notice of the Government and of Parliament, the way in which these restrictions will destroy the University representation, and deprive of the franchise a body of men who, of all others, are most fitted to exercise it.

The restriction proposed would be, in effect, so scandalous, that we can only attribute it to ignorance or oversight on the part of those who devised it. When we state that there are some 3000 medical graduates of St. Andrews in Great Britain, all of whom have passed a stringent examination in every branch of the Profession, the immense majority of whom possess other medical and surgical diplomas; many of whom hold the highest appointments in our hospitals and colleges; but only some 30 or 40 of whom would, by this bill, be entitled to vote, we have said enough to prove that the most bigoted supporters of every species of electoral corruption will have the greatest difficulty in defending the proposal. The restriction is, in point of fact, so outrageous, that we cannot for a moment believe that either Lord DERBY or Mr. DISRAELI can be aware of the manner in which it will operate; and we repeat that it would be better to have no University constituencies at all, than that, under pretence of granting them, the General Council should be erected into close boroughs, with only their own interests to serve and their own monopolies to uphold.

The Medical Profession knows to its sorrow what corporations are capable of. Do we not daily groan under the incubus we are obliged to support? Are not most of our corporate bodies governed by a select self-elected few, who constitute themselves in each case into an irresponsible power, and resist every effort for reform? They impose upon us grievous and heavy burdens, but they themselves will not move a little finger to help us to bear them. They sap the life-blood of the Profession and absorb its wealth—for what? To support their own dignities, and keep up their corporate monopolies. When we did obtain a so-called Medical Reform Bill

in 1858—what was our gain? Another corporate body created—the Council. To represent—whom? The old corporations—that is, their governing bodies, for out of these was it made. They provide its constituent parts; they regulate its action; they, through it, defend their own interests and perpetuate their own monopolies, while their members—the great body of the Profession—are left out in the shade. Yet, no! there is one exception! One thing is graciously permitted us, which is not only not monopolised by the corporations, but is not even *shared* by them. We have the one great privilege of *paying* for all this.

---

THE claims on our space by the valuable Reports to the College of Physicians of Ireland, on the new Epidemic, and by the important proceedings of the General Medical Council, as well as the Reports of the Irish Medical Association, and Royal Medical Benevolent Fund Society of Ireland, which appear in our Irish Edition, compel us to withhold our own comments on the *res gestæ* of these assemblies. The very full reports which we are enabled to give, will enable our readers to follow us in our observations on them next week.

### Notes on Current Topics.

THE NEW PHARMACOPEIA OBLIGATORY.—We beg to draw the attention of our readers to the fact that the Medical Council has directed the necessary advertisements to be inserted in the London, Dublin, and Edinburgh *Gazettes* of Friday, June 14th, from which date all the formalities prescribed by Parliament having been complied with, the new Pharmacopœia of 1867 legally supersedes all other Pharmacopœias whatsoever, and its use becomes compulsory.

MEMORIAL TO THE HOME SECRETARY.—The Manchester Statistical Society, of which Mr. D. Chadwick, is the President, has memorialised the Home Secretary in reference to the Registration of Births and Deaths, and the appointment of Officers of Health. The memorialists, amongst other things, complain that there is no compulsory power to obtain a scientific record of the cause of death, and no security in the Registration Act, against fraudulent statements and the concealment of crimes of violence: That still-born children are not registered, and the omission has notoriously facilitated the burial of children as still-born, who have been born alive: That infanticide has greatly increased, and the grave too often conceals the evidence of secret poisoning: That there is no efficient check upon the district Registrars: That scientific medical assistance in Coroner's Courts is only sought where there is suspicion of foul play, and in ordinary cases the cause of death returned by the Coroner is necessarily inexact. They suggest the appointment of skilled officers of health, with a liberal salary, who would control the sanitary measures of the district, and might also assist the Coroner in certain particulars—become, in fact, *experts*, somewhat after the

\* The report of their meeting, although in type, is unavoidably postponed.

manner proposed by Dr. Lankester, and noticed in our leading article a fortnight ago. The value of such appointments is incontestable, but the manner in which they should be made, though stated to demand careful investigation, is not considered in the memorial.

**THE LONDON COLLEGE OF SURGEONS.**—As we anticipated, Mr. Solby, of St. Thomas's Hospital, has been elected to the seat on the Board of Examiners vacated by Sir Wm. Lawrence. Some attempt at opposition was made, but proved quite ineffectual—the more so, we believe, since Mr. Solby has the character of a reformer; and so far, the members of the College may be congratulated on his success. Of his fitness for the post it would be superfluous to speak. He has been a teacher and Hospital Surgeon long enough to have rendered his merits known to the whole Profession. Considerable interest is exhibited in the other elections that will soon take place, and a sincere hope is generally expressed for the progress of reform in the College.

**QUEEN'S COLLEGE, BIRMINGHAM.**—This College was first established as a School of Medicine by several gentlemen of Birmingham, in 1828, and a hospital in connexion with it was built by public subscription in 1842. In the following year a Royal Charter was obtained, and the School changed into a College, under its present name. Large endowments were afterwards settled upon it by the late Dr. Warneford. A department in Arts, and another in Theology, were provided, and, by Royal Charter, at different times a corporate body was appointed and authorized to hold property for the support of both College and Hospital, and all proper regulations made for the government of the College, as well as the appointment of the Chaplain and the Medical and Surgical Staff. The Charity Commissioners found the College on the verge of bankruptcy, and applied to the Court of Chancery for a new scheme to be settled by the Master of the Rolls. Two of the trustees objected to this scheme, but the Lords Justices of Appeal approved of it, after two material alterations had been made by them.

**THE CHOLERA CONFERENCE AT WEIMAR.**—This conference seems to have been very successful. After fully discussing the spread of the disease, and the various modes of disinfection, the meeting proceeded to point out the direction in which further investigations should be made, and agreed that there should be—(a.) the relations of the lower animals to cholera; (b.) the influence of water, whether used for drinking or household purposes in extending the disease; (c.) the nature of soils, &c.; (d.) the influence of contact to determine whether cholera may be conveyed by goods, articles of dress, &c., from place to place; (e.) the effects of the epidemic influence; (f.) the spread of the disease by ships; (g.) the possible influence of merchandise in spreading the disease. The enumeration of these points deemed worthy of further research by the conference cannot fail to interest our readers.

**THE RIVER LEA.**—In consequence of the outbreak of cholera last summer in the East London District, this river was selected for early inspection by the Royal Commissioners on the pollution of rivers. From this source the half of London receives its supply of water, which was found to be polluted by the sewage of the different towns situate on the banks of the river, almost from its fountain-head, so that, by the

time the stream had reached the metropolis, it had become filthy to an unknown degree. The Commissioners believe that no attempts hitherto made to cleanse it have succeeded. The following are their principal suggestions on this subject, which has a bearing so important upon the health of half this great city:—1st, The casting of sewage into the flowing water must be prohibited. 2nd, The question whether a navigation should be allowed to continue in a conduit for water destined for the supply of the metropolis is one which deserves serious consideration. 3rd, The appointment of a good working Conservancy Board, on which the Government should be represented as well as the water companies, the navigation and trading interests, and the city corporation. Lastly, They recommend that the companies be compelled to supply water upon the "constant system" throughout their districts.

**DEATH FROM CHLOROFORM.**—Dr. Lancaster held an inquest at University College Hospital on the body of a little girl named Florence Lennox, nine years of age. Her mother, the widow of a gardener near Oakham, Rutlandshire, brought her to the Hospital to have an operation performed for the cure of squinting. She was in perfect health at the time. Chloroform was administered by Mr. Gill previous to the operation, which was performed by Mr. Stretchfield; and death took place upwards of two hours after. Dr. Sydney Ringer said he was present almost immediately after the chloroform was given. The patient was insensible and pulseless. She breathed heavily at intervals. He found, from post-mortem examination, that the body was well-nourished, that the heart was flaccid and contracted, but all the other organs healthy. He had no doubt the cause of death was syncope, from the administration of chloroform. It appeared that it was slowly and properly given—and not too much in quantity, and Dr. Ringer considered that there was some peculiarity of constitution in the case. They had used chloroform, he said, in that institution on thousands of patients, and had only met with one previous death about five years ago. The verdict of the jury was "Death under the administration of chloroform through misadventure." This case is of unusual interest in its bearing in the opinions of Caspar respecting slow poisoning by chloroform.

**THE ELECTION OF COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF IRELAND.**—On Monday last, being the first Monday in June, the College assembled to proceed to the election of a President, Vice-President, and Council, to serve for the ensuing year. Previously to the sudden and lamented death of Mr. Banon, the Vice-President, the programme which we foreshadowed in our last was that which it was anticipated would be adopted. That event, however, not only threw open the Presidential chair, but caused a further vacancy on the Council, which opportunity with that occurring from the retirement of Dr. Pentland, induced many candidates who had not previously announced their intention of offering themselves to do so. For the Presidency Mr. Adams and Mr. J. Hamilton competed, while for the Vice chair Mr. Porter offered himself. Mr. Macnamara also had laid his pretensions to the Vice chair before the electors, but subsequently withdrew from his candidature. For the two vacant seats on the Council the following nine gentlemen tendered themselves:—Mr. Butcher the outgoing President, Mr. Bigger, Dr. Darby of Bray, Mr. E. Hamilton of Stevens's Hospital, Dr.

Zachariah Johnson of Kilkenny, Dr. Kirkpatrick, Dr. E. D. Mapother, Professor of Anatomy and Physiology in the College, Mr. Shannon, and Dr. H. H. Stewart of Lucan. As may be presumed, the contest was a warm one, and the attendance of electors very large—100 votes having been recorded. At three o'clock, the College proceeded to a scrutiny of the ballot-box containing the votes for the Presidency, from which it appeared that Mr. Adams was elected by a large majority over Mr. Hamilton. Mr. Porter was chosen Vice-President, and Mr. Colles Secretary of the College without opposition. The scrutiny of the votes for Council occupied more than two hours, and resulted in the re-election of the out-going Councillors, with the addition of Mr. Butcher, the ex-president, and Mr. Mapother, in lieu of Mr. Adams and Dr. Pentland.

### MEETING OF THE GENERAL MEDICAL COUNCIL OF EDUCATION AND REGISTRATION.

(Continued from page 535.)

Dr. ANDREW WOOD—I agree with what Mr. Syme has stated, that it will never do for this Council to take anything but an independent and a strong course in this matter. I have no hesitation in saying that we have great reason to complain that the Home Office (whether under the past or present Government) have not paid that attention to this Council which, from its position, it deserves. Nay, more, if I understand Mr. Walpole's communication, he endeavours to throw upon the Council the blame of the delay that has taken place, in consequence of our not adopting the clause which was sent to us by Sir George Grey. Did Mr. Walpole give us the least idea of that months ago when we waited upon him? Did he say to us, "The reason why I do not take up your Bill is because your clause is not satisfactory?" If he had told us that we should have known what to do. But we were put off from day to day without any reason being given; and now that the Act comes back, we are called upon to adopt a clause which, I have no hesitation in saying, virtually goes to unseat the Medical Council, and deprive it of the power of regulating the registration of the profession, making it co-ordinate, if not subordinate, to the Foreign, Home, and Colonial departments. I would rather have no Bill at all. I would throw the Bill over the table, and cast upon the Government the blame of allowing a state of things to continue, which inflicts a hardship, not upon the medical profession chiefly, but upon the public, who, if the Government will not take up this Bill, will still have men practising among them, who assume titles, implying that they are physicians or surgeons, and commit serious damage upon her Majesty's lieges. I believe it would be better to go to Lord Derby himself, and state exactly what has happened with regard to this matter, and state at the same time, that this Council cannot accept the proposal that has been made, and cannot undertake the duty sought to be imposed upon them by two Governments, of finding a private member to bring in a public Bill. I trust we shall now take our stand, and that whatever happens we shall stand well with the public and the profession, as having done our duty, let the Government excuse itself as it may.

Mr. SYME.—My motion is—"That the President be requested to intimate that the Medical Council cannot entertain the proposal which is contained in the last communication of Mr. Walpole, to the effect of authorizing one of her Majesty's Secretaries of State to insert the names of foreign practitioners in the Medical Register."

Mr. CÆSAR HAWKINS.—The differences of opinion that appear to exist with regard to the course we should take, show the absolute necessity of adopting Dr. Paget's proposal for a Committee. If you decide upon sending to Mr. Walpole (and he and Sir George Grey are the only

persons with whom we have to do), the question will arise—"What will you do next?" And if you decide upon going to Mr. Hardy, the question will be—"What do you propose instead of this?"

Dr. SHARPEY—I agree with Mr. Hawkins. I do not think that it would be a practical or useful course to go to Lord Derby, or any one else, simply saying—"We refuse the proposal." It would be better to appoint a committee.

Dr. A. SMITH supported the motion for the appointment of a committee.

Dr. ALEXANDER WOOD—I strongly support the motion of Dr. Paget. I think that our reply will have much greater effect if it is calmly and deliberately considered and prepared by a Committee, than if it bears the least appearance of having been delivered in a fit of irritation and just indignation. I also remind the Council, that when there was a strong desire on the part of the Committee to draw up a schedule such as that suggested by the Home Office of foreign and colonial bodies fit to give licenses which should admit the holders upon our register, the difficulties were found to be insuperable. In the first place, it was difficult to get information with regard to these bodies; and in the second place, we found (I have some right to speak upon this subject from having been for several years your chairman in regard to the claims of foreign graduates) that in certain countries the whole arrangements of the Universities are so different from those in our own country that, although they are called by the same name, they mean very different things. In America, for instance, a university is not at all the same sort of institution that it is here. Any two or three individuals clubbing together for the purpose of forming a school are entitled by the laws to receive the *imprimatur* of the Government, and to be constituted a Government university. Then we often have a school labouring under that worst of diseases, "impecuniosity"—which it seeks to relieve by the granting of degrees with a freedom that is not at all reputable or safe. Now, looking at all these things—looking at the great care which it requires even on the part of medical men accustomed to look into these matters, to sift the evidence with regard to these qualifications—even with the assistance of the American Consul (who had never heard the names of many of these bodies before)—looking at the proclivities of Secretaries of State and other men in power to all kinds of heresies in medicine, I say we incur the greatest possible danger, to which we should be very foolish to expose ourselves, in going on with this Bill in the face of what I may call the warning which we have received. We are not delegates, but representatives from the different bodies; but I think we have perhaps a little erred in not taking the bodies that we represent sufficiently along with us in our struggles for medical reform. You cannot take up a single number of a medical journal which refers to the Medical Council without seeing that we are taunted with not having done things which the present Act renders it impossible for us to do. The utmost ignorance prevails among medical practitioners in regard to the powers which we possess under the Medical Act; and we are continually blamed for not exercising powers which the law has not given us. Now let us throw ourselves back upon the bodies we represent and the profession generally, who feel the necessity for the reforms for which we have been contending; and let us, before our next meeting, stir them up to besiege Parliament for a proper measure, that we may be able satisfactorily to administer. I think we should proceed calmly and deliberately, and not in the hasty manner proposed by Mr. Syme; I therefore support the motion of Dr. Paget.

Dr. CHRISTISON—I think there are very few who will not feel great surprise at the proposition that has been made by the Government. I am disposed to depart from my original view, and to support Mr. Syme's amendment, referring the matter to a Committee. To that Committee I would also beg to refer the motion which it was my intention to make, carrying into effect what has been particularly alluded to by every speaker in this matter—

namely, the more general question whether we ought ever to assent to a Bill being brought into Parliament for an amended Act, except by the Government. I feel that there is one sufficient reason why we should never do so, that we have no chance of carrying such a Bill, and under the present circumstances our chance is utterly hopeless. It is right that the Government should know this, and it is plain that they do not know it, otherwise such a proposition would never have been made to this body. It is now twenty-five years (in 1842) since a measure of medical reform, as it was then called, was taken up by Sir James Graham. It was repeated in 1845; and upon every occasion when an attempt has been made to bring in a Bill, it has been found that however private members might move in the matter, we were always obliged to give way, and to allow it to be brought in as a Government measure. Not only was this Act eventually carried by Government, but there have been no fewer than four amendments carried through Parliament, every one of which has been brought in by Government. Now what is to be concluded by the public and by legislators if they find that now, when we are coming for more important amendments than any hitherto proposed, the Government deserts us? How is it possible that we can expect to carry our Bill under such circumstances? I hope that the Committee will consider this question, which I have put in the form of a very moderate resolution—"That the Medical Act of 1858 was introduced into the House of Commons by the Government of the day; that the four amended Acts, which have since been carried, were introduced by Her Majesty's Government for the time being; and that this Council see insuperable objections to any attempt now being made to carrying new and most important amendments otherwise than by a Government Bill.

Mr. HARGRAVE said he considered that the Council had been completely "snubbed" by Mr. Walpole. He thought, however, that the Council ought not to think too lightly of the aid of private members, who on previous occasions had rendered great assistance. It would be much better for the Council to throw its pride overboard, and to apply to some honourable members of the House of Commons to assist them in the matter. They ought not to stand too much upon their dignity, or refuse such aid.

Sir D. J. CORRIGAN, Bart.—We are all, I think, unanimously of opinion that the course pursued towards us is one that ought not to have been pursued. I dissent altogether from Mr. Hargrave's proposition, and I think it would not be consistent either with our own dignity, or with our previous resolutions, or with the great interests involved in this question, to go hat in hand soliciting votes in the lobby of the House of Commons. Whatever amendment Bill is to be brought in, must be brought in by the Government; and if the Government do not choose to bring it in, let the evils that arise out of imperfect legislation lie at their doors. Last year we passed an unanimous resolution—"That it be delegated to the Executive Committee to confer with the Government in regard to the proposed Bill for the Amendment of the Medical Acts, to press on the Government the expediency of its being adopted as a Government measure; and, at the same time, to state that the Medical Council are of opinion that unless the Bill be introduced by the Government, it would be unadvisable to proceed with it." To that resolution I most strongly adhere. The question is a very narrow one, relating to a single clause from which we all dissent: that authority should be given to a Secretary of State to decide on a man's knowledge of midwifery or of medicine, is utterly absurd. We should be nothing but the mere registrars of the will and pleasure of the Secretary of State, who might any day send us down a declaration, that his nurse, or that some relative of his had informed him that Dr. Mary Walker was an exceedingly intelligent practitioner, and that he forthwith desired her name to be put upon the register. With regard to the proposal for a Committee, I shall give it my full support on one condition, namely, that the Committee shall consist of the whole Council, following the course we

have pursued on two or three former occasions. I would offer as a suggestion for the Committee, following the example of Dr. Christison, the following resolution:—"That on consideration of the great interests involved in the question of medical reform, both to the public and the profession, the General Medical Council must adhere to their resolution of May 29, 1866, namely—that the Medical Council are of opinion that unless the Bill be introduced by Government it would be unadvisable to proceed with it; and that the General Medical Council must therefore decline to accede to the Right Hon. Mr. Walpole's suggestion, that the introduction of the amended Medical Bill should be confided to some independent member of the House of Commons."

Mr. SYME said he would withdraw his amendment, and consent to the appointment of a Committee.

Dr. ACLAND—I must express my dissent from what fell from Mr. Hargrave. I quite agree with what Sir D. Corrigan and others have said, that for us to bring in any amendment Bill after so many years of existence otherwise than through the Government, would be virtually altering our position, and taking a course which would be quite suicidal. I would rather remain for any reasonable time in fact, for any time—until we have by our own power and weight in the country obtained a proper Bill.

Dr. QUAIN said that by the proposed clause the British qualifying bodies were put in a far worse position than the foreign bodies, who were proposed to be admitted by a simple application to a Secretary of State, and without any reference to the Privy Council. The answer to Mr. Walpole, and the question of the course to be subsequently adopted, should be kept distinct. He would propose, "That a Committee be appointed to prepare the draft of a reply to the letter which has been addressed to the President by Mr. Walpole, and that the Committee be requested to report to the Council to-morrow."

Mr. SYME seconded the proposal.

Mr. RUMSEY thought that Dr. Quain's suggestion should be adopted, so as to keep the answer to Mr. Walpole distinct from the future course of proceeding. If the whole question was referred to the Committee, he feared that the answer of the Council would be greatly delayed.

Dr. Quain's amendment having been adopted by Dr. Paget, now became a substantive resolution, to which

Mr. RUMSEY proposed as an amendment, and Sir D. J. CORRIGAN seconded, "That the Committee be not instructed to report on the amendment of the Medical Act."

Some further discussion having taken place as to the course to be pursued, the amendment was put and negatived by 13 against 6.

The motion was then carried *mem. con.*

The Committee was appointed, and consisted of Dr. Paget, Mr. Syme, Mr. Hawkins, Dr. Andrew Wood, Dr. Alexander Wood, Mr. Rumsey, Sir D. J. Corrigan, Dr. Christison, Dr. Acland, and Dr. Quain.

#### THE EXECUTIVE COMMITTEE.

A report was read from the Executive Committee, with reference to certain proposed Standing Orders having reference to the order of transaction of business remitted by the Council for its consideration.

The Report of the Committee on the proposed Standing Orders was as follows:—

"That the Committee, after full consideration of the subject, are of opinion that the adoption of these recommendations is unnecessary, as they give to the members of the Council no powers which they do not at present possess and exercise."

Dr. ALEXANDER WOOD said it was not intended by the proposed Standing Orders to give the Council any new powers, which could only be conferred by the Act of Parliament. He wished to state for what purpose he proposed those resolutions. When a Report was brought up before them it was read generally clause by clause, and imme-

diately every man amongst them who thought he was acquainted with English grammar would begin to criticise the grammatical composition of the clause. Then, having discharged themselves of that very important duty, they would proceed to discuss the order of the sentences, to see whether they were correctly arranged in a logical point of view; and at last, having got over the grammatical and logical trial, they proceed to consider the Report itself. The Report was then printed in the Minutes, and generally had to undergo a second process of grammatical and logical revision. Now he had introduced the proposed standing orders, with the explanation that they were neither intended to extend nor limit the powers of the Council, but to define them. Should the majority of the Council agree with the Executive Committee and throw the matter overboard, it would be competent for him to move that a Committee be appointed to consider how far the Standing Orders should embrace the dealing with Reports. At present he moved "That the Report of the Executive Committee be not adopted."

Sir DOMINIC CORRIGAN—I will move "That the Report of the Executive Committee be received and adopted."

Dr. ANDREW WOOD seconded the motion.

Dr. ALEXANDER WOOD moved, as an amendment, "That the Report of the Executive Committee be not adopted and that the resolutions be added to the Standing Orders."

Dr. EMBLETON thought such a set of Standing Orders was very much required. There was nothing like them in their existing Standing Orders; and if anything could show more clearly than another the necessity for such Orders, he thought it was the blundering method in which the business had been carried on during the last few minutes. He would second the amendment.

Mr. PAGER thought that the suggestions of Dr. Alexander Wood were very good in themselves, but he was rather averse to making them Standing Orders, from which they could not deviate without the express permission of the Council.

Sir DOMINIC CORRIGAN said, whatever blundering the Council had exhibited in the management of public business the Chairman would be held responsible for. With regard to the first resolution, had any one ever doubted that it was fully competent for any member of the Council to move that a Report be or be not received? Then as to the next, who ever doubted the power of a member of the Council to move that a Report be recommitted? They might as well pass a resolution that any member of the Council be entitled to walk up stairs. The third resolution was not only unnecessary, but objectionable, because it would absolutely bind the Council to place the mover and seconder of the motion on the Committee, which might not always be desirable.

Dr. STOKES defended the Council from the charge that large portions of their time were occupied with grammatical disquisitions and questions of logic. As a member of the Council he repudiated any such statement.

The amendment was put and lost—3 voting for, and 14 against it.

#### THURSDAY, 30TH MAY.

To-day the Council took into consideration the case of Mr. Forman, who was accused of having become registered through the instrumentality of a false affidavit, which asserted he was a member of the College of Surgeons.

Mr. Forman did not appear although he had been summoned, and, after hearing some evidence, the Council ordered his name to be erased from the Register.

Dr. ANDREW WOOD then proposed—

"That a Committee be appointed to consider and report upon what ought to be the new course of Professional Education to be gone through by all persons seeking entrance into the Medical Profession, in order to secure the possession by them of the requisite knowledge and skill for the efficient practice of their profession."

He said the same amount of attention had not been paid to professional as to preliminary examination, and he

thought it was one of the functions possessed by the Medical College to determine what standard they should erect, which would qualify students who presented themselves for examination to be placed upon the register. Much uncertainty at present existed amongst the licensing bodies, as to what was the precise curriculum of study enjoined, and this uncertainty, he thought, had created, and was likely to create, so long as no uniform system existed, much embarrassment, both to the student and the licensing bodies generally, and he maintained that if the Council appointed a Committee to sketch out the subjects on which each student would be required to be examined, he would know beforehand exactly what would be required of him before he commenced his studies. The Council would then be in a position to determine upon one uniform system of education to be adopted by all the recognised medical schools.

In seconding the resolution of Dr. Wood,

Dr. PARKES hoped the Council would not waste their time by a discussion upon the question of one uniform system, as he considered the mover had made out a sufficiently good case, that the advantages must be patent to all.

Dr. STORRAR said, Dr. Wood and Dr. Parkes had made their speeches as short as possible, evidently desiring there should be but little discussion on the motion then before the Council; he (Dr. Storrar), however, begged to differ from those gentlemen, and hoped the Council would allow him to state his views, and the results of his experience on the questions at issue. He was well aware that there existed many and diverse opinions among the licensing bodies. Some would limit the number of courses requisite for study, others doubted the utility of any particular curriculum; another body insisted that the study of one or two important subjects, would fit a man for the practice of his profession in after life. Again, some of the schools commenced their session in October, others in November, whilst a few thought the term should open with a summer session. Then, there were tedious discussions about long and short courses, so that it became impossible to adopt one uniform system. Even supposing it were possible, he very much doubted its desirability. At first sight, there was something so tempting in the idea of uniformity, that it almost seduced one to believe everything in the way of education could be reduced to this system. For the last three years, he had given great attention to the subject of education, and from information gathered throughout the United Kingdom, combined with that officially obtained from a Special Commissioner sent to the Continent, for the purpose of getting the views there entertained, he believed that the Council would make a great mistake if they introduced a uniform system of education. In France, where it was most perfect, so perfect in fact, that it moved like a machine throughout the country, and where the Chief of the Department could at any time look at his watch, and say he knew what lectures were at that hour being delivered over the whole Empire—it was a signal failure, on account of the perfection of the system. In the present curriculum, the Council had the master-piece of medical education—the preliminary examination in Arts; then there was the four hours of prescribed studies—the visitations of examinations, with power of improving them, &c. But to require that every man should attend so long at Hospital practice, give so much time to bandaging, midwifery, and other subjects, whether he would ever require them or not, he thought was a great mistake. Opinions on the training of minds for professional pursuits were so diverse, that he sincerely hoped the Council would not think of passing the measure before them.

Sir DOMINIC CORRIGAN would vote for the motion of Dr. Wood, if he would agree to omit the words "professional study," because, in many branches of study, such as midwifery, it would be utterly impossible to draw up any prescribed rules. He knew that in many Colleges, irregularities as to time of study, attendance at lectures, examinations, granting certificates, &c., already existed, and he thought

if this uniform system of professional study were adopted, a much larger field would be open for these proceedings.

Dr. ALEXANDER WOOD remarked that Sir Dominic Corrigan's usual mode at that Council was to erect a man of straw, in order that he might have it to knock down. He seemed to persist in opposition, so that he had little hope of bringing forward any measure with an idea of success, when such determined opposition to progress was made. He was glad to see the Council did not all entertain the same views as Sir Dominic, and he thought that if such obstructions were to be continually thrown in the way, it was useless to proceed.

Mr. HARGRAVE said the working of the machinery of education, as at present adopted in the schools of Dublin, was eminently satisfactory; but he thought if something more were determined upon, in the character of the examinations, it would be a great boon.

Mr. CÆSAR HAWKINS thought it would simplify matters if the words "and examinations" were omitted in the motion.

Dr. ANDREW WOOD had no objection to this course.

Dr. SHARPEY was sorry that the wish to pass such an iron rule upon students should ever have been entertained by any member of the Council. He thought the proposal carried its own defeat.

Mr. PAGET suggested that a committee should be appointed to consider the question of professional study. He thought it would be a very unwise measure to compel every student to go through one and the same course of study.

Dr. ACLAND was impressed with the same ideas. He quite agreed that there should be a minimum standard of education; for a student who could not perform the simple operation of cupping a patient, would certainly not be fitted for the higher branches of his profession. He thought it would greatly expedite matters if committees were appointed to report to the Council the curricula on three subjects, so that the Council might be able, by collective wisdom, to decide upon the minimum standard to be adopted.

Mr. RUMSEY strongly objected to one uniform system of education for the reasons already stated, and for others which he entertained, but he quite agreed that there should be a minimum standard of education. The enforcement of the measure proposed would be most unphilosophical.

Dr. RISDON BENNETT said the difference existing in his mind, between a fixed and a minimum standard of education, was very great. He did not see why a student for the College of Physicians should be compelled to go through the same course—to devote the same time to the study of surgery and pharmacy, before he could go up to the Examining Board as a student for the College of Surgeons. He thought it would be foolishness, in the extreme, to lay down any fixed course of study.

After some further remarks by Sir D. Corrigan, Dr. Christison, Mr. Rumsey, Dr. Wood, and Dr. Acland, the discussion was adjourned to the next day.

#### FRIDAY, 31ST MAY.

Dr. RISDON BENNETT resumed the discussion on Sir Dominic Corrigan's amendment, adjourned from the preceding day, proposing as a substitution to that of Sir Dominic Corrigan:—

"That the Council having decided what should be the extent and character of the Preliminary Examination, it is incumbent upon them to consider and report on the amount and character of professional study absolutely necessary for securing the possession of the requisite skill and knowledge by all persons seeking entrance into the medical profession, and that a Committee be appointed for that purpose."

After discussion, in which Mr. Syme, Dr. Alex. Wood, Sir D. Corrigan, Dr. Fleming, Mr. Rumsey, and Dr. Andrew Wood took part, the amendment was lost.

The amendment of Sir D. Corrigan was also put from the chair, and negatived.

When Dr. QUAIN proposed a second amendment seconded by Mr. SYME:—

"That a Committee be appointed to consider and report to this Council what are the subjects, without a knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered."

Which, having been carried, was put as a substantive to the original motion of Dr. Wood, and agreed to. The Committee to consist of the following members:—Dr. Quain, chairman; Dr. Bennett; Mr. Hawkins; Dr. Storrar; Dr. Andrew Wood; Mr. Syme; Mr. Hargrave; Dr. Sharpey; and Dr. Stokes.

It was then moved by Mr. HAWKINS, seconded by Dr. PAGET, and agreed to:—

"That the reports of the visitors of examinations be received and entered on the minutes, and that a copy be sent to each of the bodies named in Schedule (A) to the Medical Act."

Dr. ANDREW WOOD then rose, pursuant to notice, to propose the following motion:—

"That the reports of the visitations of examinations during the past two years, be referred to a Committee, whose duty it shall be to go carefully through them, and to bring before the General Medical Council, during their present Session, a report embodying such recommendations, founded on the various suggestions made by the visitors, as may tend to improve generally the examinations for the licence to practise medicine and surgery, and to remedy the defects in particular examinations which have been pointed out by the visitors."

Dr. Wood said he would not detain the Council with any lengthy remarks on the motion he had brought before them, as he thought there could not possibly be any great opposition to the measure proposed. They had seen and heard a great deal of evidence on the subject, and comment on that evidence had been very freely indulged in. But, looking at the encouragement the Council had received from the visitations, and the evidence before them, the motion, he anticipated, would be adopted by a large majority.

Dr. STORRAR begged to second the motion.

Mr. HAWKINS thought it a very praiseworthy measure, and one which must eventually be adopted, but he doubted the desirability of its being passed in the present session of the Council. It was of so much importance, that they should not be hasty in dealing with the matter, and he hoped the Council would hesitate before sanctioning its adoption.

Dr. PARKES was of a different opinion. He thought the Council should not hesitate to appoint a Committee for the immediate consideration of the motion; nothing could possibly be gained by delay, whilst much valuable time might be lost.

Dr. STOKES and Mr. HARGRAVE were of the same opinion.

The motion was then put and agreed to—the Committee consisting as follows:—Dr. Andrew Wood, chairman; Mr. Hawkins; Dr. Paget; Dr. Storrar; Dr. Thomson; Dr. Lect; Dr. Apjohn; Dr. Sharpey; Dr. Parkes; and Dr. Christison.

Dr. PAGET considered the reports, as presented, were so good, from all three divisions of the United Kingdom, that no apology for them was necessary. There were but two exceptions to make them complete, viz.—the University of St. Andrews, and the Apothecaries' Hall of Ireland, and he proposed, that in order that the Council should be in possession of these reports, two Commissioners should be delegated to visit the examinations of these bodies, and furnish reports therefrom, as the reports without them were necessarily incomplete. He then proposed:—

"That it be an instruction to the Committee to report as to the best means of supplying the few omissions in the reports of visitations of examinations now received."

This motion was seconded by Dr. THOMSON, and carried. Dr. ACQUILLA SMITH, addressing the President, wished,

with his permission, to make a few remarks on a subject which, he thought, every member of the Board would condemn. On May 25th, four days before the meeting of the Council, an article appeared in the *British Medical Journal*, commenting on one of the reports which were printed for private distribution amongst the members only, and upon the title-page of which appeared the word "confidential." He would not stop to enquire how this report got into the hands of those connected with the journal in question. It was much to be regretted that the conductors of a journal should have committed such a gross breach of confidence as to ignore the respect due to the Council, by commenting upon matters prior to their being officially brought before the members of that Board. He (Dr. Smith) hoped the President would take some notice of this breach of confidence, so that the Council, through him, might express their condemnation of so unwarrantable a proceeding.

The PRESIDENT said Dr. Smith was perfectly justified in bringing the subject before them, and he was convinced the members of the Council concurred in the remarks that had been made. It was a great breach of confidence on the part of those who conducted the journal in question; and he wished to express his entire disapproval of the unusual course that had been adopted. If the Council agreed with the remarks that had fallen from Dr. Smith and himself, he would request the Registrar to place a notice of the same upon the minutes.

This proposal having been assented to, the Registrar was requested to place the same upon the minutes of the Council.

Dr. ALEXANDER WOOD then gave notice that, with the permission of the Council, he would withdraw his motion inserted upon the programme of proceedings, which was:—

"That, with the experience the Council have had during the last two years in conducting the Visitation of Examinations personally by members of the Council, it is desirable that the expediency of the alternative method provided in the Act be now considered.

"That with this view, the Council do, during the present Session, reconsider the report of a Committee on 'Visitation of Examinations,' laid before the Council 21st June, 1860, and printed in the Minutes, vol. i., pp. 125-6." And would substitute the following:—

"That a Committee be appointed to prepare a scheme for the Visitation of Examinations of next year, and especially to consider the best means of supervising the Arts' examinations."

Dr. Wood said he knew the present proposition would meet with the same obstructions that had been before advanced when this subject had been brought forward, and in the course of an elaborate speech, severely censured those members who had hitherto refused to act at the Visitations of Examinations. He declared that whereas one or two had declined to do their duty—a duty, moreover, which he considered was incumbent upon them, though not compulsory, by the Act of Parliament he cited—another member (Dr. Smith) was afraid to act because the College (the College of Physicians of Ireland), for which he was the accredited representative, refused its sanction, on pain of dismissal from continuing to be a member of their Council.

To this personal attack, Dr. SMITH rose to give the statement the most unqualified denial, declaring that the remarks of Dr. Wood were simply and essentially untrue in every particular.

Dr. WOOD concluded his remarks by stating that so long as individual members of that Board refused to perform what he considered to be their duty in this important matter, it being imperative that it should be performed by some one, nothing satisfactory could possibly ensue. He maintained that, as different Bodies conducted the Examinations in different ways, there must necessarily be two ways of doing them—one right, the other wrong. The question before the Council was, which was the right one.

Let them, then, thoroughly examine the matter as it stood—let the Committee prepare the scheme, and then they would know what they were about, and not be pulling one against the other, or, like Tony Lumpkins, be trotting round and round a circumscribed area, without daring to go manfully and resolutely at the point.

Sir DOMINIC CORRIGAN rose and said that a member of Council had yesterday observed that there was great blundering in the mode of carrying on the business of the Council. He was sorry to be obliged to-day to endorse that observation. One of the causes of the long and desultory discussion arose from what he could not avoid saying was a most irregular proceeding—viz., Dr. Alexander Wood being allowed to withdraw his notice of motion on paper, and substitute for it a motion of a totally different character, and altogether unconnected with it in substance. He must, before going into discussion on the question now before them, notice the very unwarrantable attack of Dr. Wood on the President and Fellows of the King and Queen's College of Ireland, when he said that no man in his senses could believe that in the letter written by that College, the Fellows of the College stated the truth as to their reasons, and that it was obvious what was stated by them was merely a pretence to conceal their true reasons and motives. The Fellows of the College of Physicians of Ireland were equally indifferent to his praise and his censure, and they would regard both with equal contempt. Dr. Alexander Wood had found fault with him in having always refused to take any part in the Visitation of Examinations, and had, moreover, charged it as an aggravation that while he (Sir Dominic) had persistently refused to take any part in the visitation of examinations, he had never condescended to explain his reasons to the Council. He hoped that, on merely calling to the recollection of the Council what had occurred, Dr. Wood would himself remember that when he was first asked to take part in the visitation of examinations, he felt it necessary to explain his reasons and he did give his reasons at great length, and as these reasons were already stated in the published reports of their debates, he would not occupy the meeting with a repetition of them further than to repeat one observation he had then made—that in principle the system was rotten of A. inspecting the examination conducted by B., and of B. conducting the examination by A., and then A. and B. interchanging their reports on each other. He had spoken in his former observation of the visitation of examinations as a farce. He must, he regretted to say, go further, and say that he now considered it as a cheat and a blind on the profession and the public. These facts came before them in the proceedings of yesterday that the College of Physicians of Edinburgh had two doors to its hall of examination—one at which candidates were admitted on public days, and paraded as show-girls are paraded at boarding-schools on their public days for the admiration of visitors—days on which the visitors appointed by the Council are notified to attend, but another door for what are called by Dr. Wood "exceptional" cases, for examinations to which the visitors have never been summoned, and conducted in private at a different hour—at six o'clock in the evening,—and that the candidate for this private examination pays double fees. Thus the candidate who fears to enter the front door when the visitors of examinations may be present, is desired to wait behind the second door and told that when eyes that might be troublesome are away he could then slip in and get his examination in strict privacy and his diploma, provided he only paid a double fee. With such a system as this, surely he was justified in the view he entertained that the visitation of examinations is a cheat and a blind. He (Sir Dominic) did not know sufficiently the regulation of the College of Physicians of England to speak of them, but in regard to the College of Physicians in Ireland he must set Dr. Wood right. There are special examinations, but here all resemblance ceases. There is no double fee paid for the examinations at the College of Physicians in Ireland, making it their interest

to have as many as possible of those private examinations. There is no privacy. In Dublin alone there are of Fellows and Licentiates about 150 or 200, exclusive of those attached to the garrison. The College is always open, with its library and reading-room. The notices of every examination are posted in the Entrance Hall. The examinations are open to all Fellows and Licentiates—the President presides. There is in this public examination the true, and, he believed, best safeguard for a good examination, and for a true verdict. He (Sir Dominic) could now understand the very prominent opposition presented by Dr. Alexander Wood, to the proposition discussed on a former occasion, of having examinations public, as they are conducted in the University of Dublin, in the Royal College of Surgeons Ireland, and in the King and Queen's College of Physicians Ireland. Publicity would spoil a system of double fees and partial examinations. He would now condense his grounds of objection to Dr. Alexander Wood's motion into these short observations—that it was a substitution for the motion on paper of another having no relation to it; that it came upon the Council by a surprise; and that, by a side wind, it virtually repeated, without any previous notice, a resolution in the minutes, that the Branch Councils were the bodies to carry out those visitations. All these were reasons, in addition to the views which he had always taken, that a system that in principles was bad, can never be made right in details. He would now conclude, by merely drawing the attention of the Council to the fact, that while Dr. Andrew Wood was very severe on the Branch Council of Ireland, for having omitted to visit the examination at the Apothecaries' Hall of Ireland, the Branch Council of Scotland, (of which fact, of course, he took no notice), were in a worse predicament, for there was no report from it of any visitation to the examination of the College of Physicians of Edinburgh, or of the University of St. Andrews.

Mr. RUMSEY regretted exceedingly, that such unmeasured language should have been used. He was one of those members who had refused to act, for reasons well known to the Council. He maintained there was no legal compulsion contemplated in the Act which Dr. Alexander Wood had quoted; and one reason for his declining to act was, because of the existence of an alternative, which alternative he should firmly adhere to, until the visitations were more thoroughly conducted. He considered the visitations should be undertaken by persons not belonging to the Council, and that visitors, inspectors, or examiners, as they might be termed, should be appointed, similar to those at the Government Educational Establishments, who should be constantly at work—without partiality or injudicious opposition. Until this were done, no permanent good could possibly be arrived at, and no satisfactory objects attained by the visitations so strenuously and persistently upheld by Dr. Alex. Wood.

Dr. WOOD explained that he did not mean to infer there was any compulsion in the Act quoted by him, it was merely, in his opinion, a matter of duty. He much regretted Mr. Rumsey had refused to accept only part of his explanation relative to those members who had declined to act in the visitations. Sir Dominic Corrigan had also, in his most vehement speech, taken the Universities of Edinburgh to task, in his usual ingenious manner. These bodies seemed to the hon. baronet, a stronghold for every attack, and a point for every joke, in the arguments which he continually brought to bear on the subject. To this speech, however, he would be sorry to reply, as it might again lead to personalities and retorts, which would be anything but agreeable or entertaining.

Dr. PARKES observed, that as he heard no tangible objections advanced against the substitution of the present for the original motion of Dr. Wood, he considered the same to be practically unopposed. He would, therefore, in seconding the resolution, suggest the appointment of the Committee.

The resolution having been put and carried,

It was moved by Dr. EMBLETON, seconded by Dr. STORRAR, and agreed to—

“That a Committee be appointed to report upon—1. The Registration of Medical Students. 2. The returns from the bodies in Schedule (A) of professional examinations and their results.”

The Committee were nominated—and the proceedings adjourned till Saturday.

SATURDAY, 1ST JUNE.

On this day the sittings of the Council commenced one hour earlier than usual, but little business was got through, an hour and a-half being consumed in the discussion of points relating to the etiquette of the Council Table, upon invidious remarks and personalities, which it would be idle for us to chronicle, and worse than useless to our readers. We give the business transacted in full; refraining from introducing any of the speeches or remarks that were made during its process, as they were merely of a desultory character, and would occupy more space than we are able or think it essential to give:—

It was then proposed, “That it would expedite the business of the General Medical Council, and tend to shorten the length of its Sessions, were the Council to adopt Resolutions to the following effect, viz:—

‘1. That the Executive Committee should consider and prepare Reports upon any subjects that may suggest themselves to the Committee, as requiring the attention of the General Council.

‘2. That such Reports should be printed and circulated among the members of the General Council, at least one fortnight before its meeting.

‘3. That the Branch Councils be requested to transmit to the Executive Committee the Reports of the Visitation of Examinations, at least one month before the meeting of the General Council, in order that they may be printed, and circulated among the members of the Council.

‘4. That the Executive Committee meet before the annual Meeting of the General Council, in order to prepare and arrange the business for the consideration of the Council.”

Reports from each of the Branch Councils were then read to the effect—

“That it is not necessary to define more clearly the manner in which the column headed ‘Place of Medical Study’ in the form of registration of medical students should be filled up.”

The following communications addressed to the Medical Council were on the programme of business for this day, but were postponed till Monday:—

“From the University of Melbourne, University of Calcutta, and University of Sydney, praying for the recognition of its degrees.

“From the McGill University, Montreal, praying for the recognition of its Matriculation Examination.

“From the Registrar of the Medical Council of Upper Canada, praying for the Registration of Upper Canadian Diplomas.

“From the President of the Medical Council of Upper Canada, relative to the recognition of certain Colonial Diplomas.

“From Dr. GEORGE BUCHANAN, Examiner in Arts to the Society of Apothecaries, relative to compulsory Examination in Greek.

“From Dr. W. B. HEPPWORTH, relative to the Medical Acts Amendment Bill.

“From the Cork Medical Protection Association, ditto.

“From Dr. JAMES MASON, ditto.

“From Dr. GIBSON, relative to the Qualification of Master in Surgery.

“Petition from HENRY B. C. MILLIER, for the Registration of his Erlangen Degree, obtained without regular Examination.

“Petition from RICHARD ORGAN, to be allowed to pre-

sent himself for Examination at one of the Examining Bodies."

"Communications from the President of the Council of the British Medical Association to the President of the Medical Council, relative to the Medical Acts Amendment Bill."

Sir DOMINIC CORRIGAN proposed, and Dr. PAGET seconded—"That the letter, with enclosure, from the President of the Council of the British Medical Association be inserted on the minutes."

The following notice of motion, by Dr. PAGET—"That the Communications from the Universities of Melbourne, Calcutta, and Sydney, and from the Registrar and President of the Medical Council of Upper Canada; also those from Dr. W. B. HEFWORTH, the Cork Medical Protection Association, and Dr. JAMES MASON and the President of the Council of the British Association, be read," was also postponed, and the meeting adjourned till Monday.

## Correspondence.

### REMOVAL OF THE ARM AT THE SHOULDER-JOINT, AT SEA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the 1st of May, 1830, after the action between H.M. brig, *Primrose*, and the Spanish slave frigate *La Velos Passagera*, I had to perform seventeen capital operations; five above and three below the knee; six above and two below the elbow; and one at the shoulder-joint. I had no Assistant-Surgeon, but I got the purser to assist me. I performed all the operations in one day, except the shoulder. I found the arm dreadfully shattered. He was in a boat on the booms, and the ship was going about eight knots; wind abaft the beam. I rolled some calico round the handle of the key of my cabin-door, and instructed the purser in its use. In cutting through the deltoid, I cut through an irregular artery, which I had to tie. When I had finished my sweep round the limb, I found the main artery untouched. I tied it at once, and relieved both the purser's anxiety and my own. I now detached the deltoid, cut the ligament, and separated the limb. I brought the edges together by stitches and plaister as well as I could, and placed a wet cloth over it. It gave me no trouble; healed rapidly. When I hear so much fuss, and so many assistants required, at such operations at public hospitals, I cannot help thinking what a fix some of them would have been in had they been in my situation—though, to be candid, I did not like it; but I had to do it, and did not lose a patient.—I am, sir, your obedient servant,

ALEXANDER LANE, M.D.,  
Surgeon Royal Navy.

### TREATMENT OF AGUE BY HEAT TO THE SPINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As many valuable and scientific articles appear from time to time in your journal on the use of cold in spinal ice-bags, permit me to give you some information on the application of heat.

Thirteen years since I was quartered at a most unhealthy station in the East, where Europeans and natives suffered fearfully from jungle fever, in the shape of quotidian ague. I became a victim also, treating myself according to the orthodox medical principles without benefiting thereby, as I could not leave my station. Reduced almost to a skeleton, my devoted native head servant took compassion on me, and said "if master would try native doctor's remedies, he soon get well." I submitted cheerfully, as it was simple. When the sun set, the cold creeping sensation of the disease regularly commenced, well-known to those who were attacked, that peculiar feeling along the course of the spinal column, and the blue marks at the root of the nails. My servant heated two common bricks, wrapped them up in several folds of cotton cloth, and applied them to the spinal-cord as I reclined in bed; the cold stage even on first application was rapidly cut short, and the warmed stage induced with intense relief to myself. He continued the treatment for a week every evening, when I had entirely got rid of my enemy. Without taking up your valuable space, I merely state this as a fact, which I subsequently confirmed by treating others in the same way

The hot bricks are rude I grant, but efficacious. It appears to be an old native remedy. Why should not hot spinal bags be used in such diseases. One of the native doctors told me that he used this hot treatment in cholera by means of braziers of hot fire, *i.e.*, live charcoal, put under the bamboo couch on which his cholera patients were laid naked, then covered over above, except the face, with thick warm clothing. The intense cramp and suffering of this unknown malady was checked remarkably with cessation of rice-water evacuations and vomiting, and the relief was invariably followed by copious offensive discharges from the bowels the next day. As this knowledge may be generally unknown, I offer it as having witnessed facts, and am a firm believer in the hot treatment of ague or cholera.—Yours respectfully,  
M.D., M.R.C.P., Lond.

## Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An advertisement appeared in the *London Gazette* of Friday, to the effect that a meeting of the Royal College of Surgeons will be held at the Hall of that Institution on Thursday, July 4, at 2 o'clock, for the election of three Fellows into the Council of the College, in the room of Mr. Frederic Carpenter Skey, of Mr. Thomas Wormald, and of Mr. Francis Kiernan, who go out in rotation, but are eligible for re-election. It is understood that these gentlemen will again offer themselves for the honour of a councillor's seat, but will meet with some opposition, as already Messrs. Holden and Spencer Smith's friends have expressed their intention of bringing these gentlemen forward.

HER Majesty the Queen has decided upon expending no less a sum than half-a-million sterling on the erection and endowment of an Asylum for Convalescents, in connection with the several Metropolitan Hospitals—more especially with St. Bartholomew's, of which the Prince of Wales is President. It is reported that about £200,000 is to be appropriated to the purchase of a site, and the erection of suitable buildings in a healthy part of the country; the remainder to the endowment. The *Standard* of Monday last confirms the report in the following terms:—"The rumour of her Majesty's intention to erect and endow a hospital in the country as a convalescent hospital, in connection with the Royal foundation of St. Bartholomew's, is quite correct, the Governors having received an intimation of the Queen's Royal pleasure through the President of the Hospital, his Royal Highness the Prince of Wales, a few days ago."

### LIST of Entries in the Branch Medical Council, Ireland, for May, 1867.

Arthur Ormsby Wiley, 14, Longford-terrace, Monkstown, County Dublin, L.R.C.S. Ireland, 1867.

John Riddell, Shantonagh, Ballybay, County Monaghan, L.R.C.P. Edin., 1866; L.R.C.S. Edin., 1866.

James Henry Ussher, Elmville, Roundtown, County Dublin, M.B. Univ. Dublin, 1866; Mastr. Surg. do., 1867.

Joseph Thomas Begge, 4, Cavendish-row, Dublin, L.K.Q. Coll. Phys. Ireland, 1866; Lic. Royal Coll. Surg. Ireland, 1866.

Charles George Lyster, Cascade House, Freshford, County Kilkenny, Lic. 1867, and Lic. Midwif. 1867; K.Q.C. Phys. Ireland; Lic. Royal Coll. Surg. Ireland, 1867.

John Ferguson, Summerhill, County Meath, Lic. Fac. Phys. Surg. Glasgow, 1864; Lic. Royal Coll. Phys. Edin., 1865.

John M'Gee M'Cormac, Ballinahinch, County Down, Lic. Royal Coll. Phys. Edin., 1867; Lic. Royal Coll. Surg. Edin., 1867.

Daniel Heagerty, Passage, West, Cork, Lic. Royal Coll. Phys. Edin., 1867; Lic. Royal Coll. Surg. Edin., 1867.

ROYAL ZOOLOGICAL SOCIETY OF IRELAND.—The Council of the Society have added to their collection, within the last week, a fine Bonnet Monkey, presented to the Society by G. Graves, Esq., 11, Tivoli-terrace, Kingstown. The animal is in perfect health, and has been placed in one of the cages of the new monkey house. The pair of pelicans lately introduced into the gardens, have been pinioned and let loose upon the lake, where, it is hoped, that they will breed. They have become familiar, so that they will come to the call of their attendant. They have returned to their original habits, and have been seen to dive to the bottom and bring up live fish in the great pouch which is attached to their lower mandible.

THE latest news from India states that cholera had prevailed seriously in Benares during the pilgrimage there; and that the disease had, in spite of precautions, also appeared among the masses of natives who had crowded to be fair at Rendwar.

**THE BRITON MEDICAL AND GENERAL LIFE ASSOCIATION.**—We avail ourselves of the occasion of the Annual Meeting of the Royal Medical Benevolent Fund Society of Ireland to remind our readers that, however prosperous that noble institution may be, it can never afford any but an auxiliary provision to that which it is the duty of every man to make for his family. The Briton claims the support of medical men on the ground that it is under the administration, to a great extent, of medical men, its Directory including such men as Fergusson, Partridge, Tyler Smith, Propert, and Sieveking.

#### NOTICES TO CORRESPONDENTS.

*Dr. Peebles.*—Your paper has been received, and we hope it will appear in our next.

We have received your letter in reply to Mr. Thompson. In the crowded state of our columns we cannot find room for further discussion on the subject, to which so much space has already been given.

*Mr. Smith.*—Received, and will shortly appear.

*Mr. W. U.*—Sorry we were unable to insert your remarks in our last issue.

### Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

#### BIRTHS.

**AINSWORTH.**—On the 26th ult., at West-grove, St. Lawrence, Jersey, the wife of Samuel Ainsworth, Esq., of a daughter.

**BASTIAN.**—On the 24th ult., at Avenue-road, Regent's-park, the wife of Dr. H. C. Bastian, of a daughter.

**BRUMWELL.**—On the 25th ult., at Mossley, near Manchester, the wife of G. M. Brumwell, M.D., of a daughter.

**JACOB.**—On the 31st ult., at Ely-place, Dublin, the wife of Archibald Hamilton Jacob, M.D., F.R.C.S., of a son.

**JAMES.**—On the 24th ult., at Perry-vale, Forest-hill, the wife of A. James, M.D., of a daughter.

**LONGMORE.**—On the 24th ult., at Hauble, Southampton, the wife of Deputy-Inspector General Longmore, C.B., of a daughter.

**SAUNDERS.**—On the 21st ult., at the Devon County Asylum, Exminster, the wife of Dr. G. Symes Saunders, of a son.

**WARD.**—On the 21st ult., at Bicton-terrace, Exmouth, the wife of T. M. Ward, M.R.C.S.E., L.S.A., of a daughter.

**WATKINS.**—On the 26th ult., at Guildford-street, Russell-square, the wife of Edwin T. Watkins, M.D., of a son.

#### MARRIAGES.

**HAMILTON—JEFFRAY.**—On the 29th ult., at St. Mary's, Windermere, Archibald Hamilton, M.D., of Windermere, to Katharine, only daughter of the late Rev. L. W. Jeffray, M.A., Rector of Aldford, Cheshire.

**POPE—NORTHCOTE.**—On the 29th ult., at St. Mark's Church, Sturbiton, Edmund Pope, Esq., Surgeon, of Steppay-green, London, to Ellen Northcote, stepdaughter of E. W. Barfoot, Esq., Surgeon, of Cadogan-road, Surbiton.

#### DEATHS.

**MOLLE.**—On the 18th ult., at Soden, near Frankfort-on-Main, John W. Molle, M.D., of Charleston, U.S., aged 35.

**RUMSEY.**—On the 13th of April, at Buenos Ayres, John Henry Rumsey, M.R.C.S., eldest and beloved son of Arthur Rumsey, Esq., of Fulham-road, London, aged 27.

**SOMERVILLE.**—On the 21st ult., at Aole Villa, Croydon, Surrey, Thomas Hope, eldest son of David Hope Somerville, M.D.

**WARD.**—On the 22nd ult., at Bicton-place, Exmouth, John Richard Ward, M.R.C.S.E., formerly Battalion Surgeon Scots Fusilier Guards, aged 57.

**WILTON.**—On the 23rd ult., J. W. Wilton, F.R.C.S.E., of Gloucester, late Senior Surgeon to the Gloucester Infirmary, aged 71.

#### NOTICE TO ADVERTISERS.

### The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Ho-pital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under .....	£0 3s. 6d.
Per line afterwards .....	0 0s. 6d.
One-quarter page .....	1 0s. 0d.
Half .....	1 15s. 0d.
One .....	3 0s. 0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the OFFICE, 3, LINCOLN-PLACE, DUBLIN, on MONDAY, by THREE o'Clock.

### COD LIVER OLEINE

FOR HOSPITAL USE.

**BEDFORD BROTHERS**, believing that a pure, good and Cheap Cod Liver Oil is one of the great necessities of Hospital practice of the present day, have arranged to supply the demand in the form of a **COD LIVER OLEINE**.

The Cod Liver Oleine for Hospital use, differs only from the Crystal Cod Liver Oleine imported by Bedford Brothers, and now so generally used amongst the wealthier classes, in that it contains a little solid fatty matter, but not sufficient to interfere with its ready digestion.

The Hospital Cod Liver Oleine, like the Crystal Cod Liver Oleine, is tasteless and inodorous.

In Tins, each 15 or 30 gallons (for Hospitals only), at 6s. per gallon.

87, Tower Hill, London, E.C.,

27th May, 1867.

### UNIVERSITY LIFE ASSURANCE SOCIETY.

EXTENSION TO FOUNDATION SCHOOLS.

Additions in 1865 at the rate of 1½ per cent. per annum.

CHARLES McCABE, Secretary.

24, Suffolk-street, London, S.W.

### NATIONAL ORTHOPÆDIC HOSPITAL.

**L**ECTURES ON DEFORMITIES will be Delivered on 11 consecutive Tuesdays, at 4 P.M., commencing May 21st, as follows:—

On Angular Curvature of the Spine. By Mr. T. Carr Jackson.

On Infantile Osteo-malacia. By Dr. Dick.

On Talipes Barus. By Mr. L. Stromeyer Little.

Free to Practitioners and Students of Medicine.

Hospital, Great Portland-street, London, W.

W. C. HARVEY, Hon. Sec.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

**T**WO LECTURES will be delivered at the College, Pall Mall East, on Friday, June 14th, and Monday, June 17th, at Five o'Clock p.m., by Dr. ANSTLE, on the PROGNOSIS AND TREATMENT OF CERTAIN ACUTE DISEASES, with special reference to the indications afforded by the GRAPHIC STUDY OF THE ARTERIAL PULSE.

(By order of the President.)

1867.

W. COPNEY.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

**F**IRST PART OF PRIMARY PROFESSIONAL EXAMINATION FOR THE LICENCE.—The next Examination of Students who have completed Two Years of Professional Study at a recognised Medical School will commence on Tuesday, July 2nd.

**SECOND PART OR PASS EXAMINATION.**—An Examination of gentlemen who are eligible for admission to the second Examination for the Licence will commence on Tuesday, July 9th.

Registered Medical Practitioners qualified before January, 1861, are admitted to Examination under Special Bye-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all certificates and testimonials required by the Bye-laws are to be left at the same time.

Pall-Mall East, 1867.

H. A. PITMAN, M.D., Registrar.

## Original Communication.

## SELECTED CASES, DEMONSTRATING THE VALUE OF ELECTRICITY AS A CURATIVE AGENT.

By HARRY LOBB.

## No. I.—RHEUMATIC PARALYSIS.

In the following series of papers, I propose minutely to describe the method of application of batteries and apparatus necessary for the treatment of each case. As I have received so many requests from medical men, for information on this head, I shall therefore briefly allude to the disease, and devote more space to the treatment. Perhaps of all the diseases that come under the treatment of the medical electrician, rheumatic paralysis is the most amenable to the judicious application of electricity. As a rule, ordinary routine medical treatment has no effect upon this malady, and the disease progresses from bad to worse, until the use of the limb or limbs is completely lost. The following case is a most instructive one, and is a fair type of this disease.

Mr. G— called upon me on the 20th of last March, with a note from Sir Wm. Fergusson, stating that "the bearer will tell you his story; my idea is that electricity may be of service, and I recommend him to you with that view," and giving the following history, in writing, which I give in his own words. "On Saturday, the 2nd of February, 1867, on returning home in the evening, I felt what appeared to me to be a light blow on my right shoulder, which ached slightly from that moment until I got into bed, the pain then increased in the shoulder, neck, and back of the head, and kept me awake nearly all night. From that time, for three weeks, I did not sleep more than two or three hours in the twenty-four. I took medicine to operate on the liver, and also efferevescing draughts to act on the skin. Vapour baths, hot-air baths at the hammam; shampooing, rubbing with stimulating oils, and douches were tried, from all of which I experienced temporary relief, but not of a lasting nature. At the end of six or seven weeks nothing but the rudimentary rheumatic pain was left.

"About the 5th of February, I began to feel great weakness in my right arm and shoulder, and difficulty in shaving and dressing. On the 10th I employed a barber, who shaved me every morning. After the 10th of March I virtually lost the use of my deltoid and biceps, but could always write when my arm was lifted and placed on the table. I saw —, who gave me a liniment of chloroform and camphor, which proved useless. Afterwards he gave me iodide of potassium, with the like result. My arm not improving in the slightest degree, I consulted Sir W. Fergusson on the 20th of March, who sent me the same day to Mr. Lobb."

On examination, I found the deltoid completely paralyzed, the biceps almost so; both much wasted and very soft; the extensor very weak.

**ELECTRICAL EXAMINATION.**—The battery I employed is my own Portable Book Electro-Magnetic Battery, made by Ladd. First using the secondary wire, or induced current of electricity, attaching a moist conductor to the positive pole, which I placed upon the spine, I examined the skin covering the affected muscles with a wire-brush attached to the negative pole, using the whole power of the battery.

Sensation was very dull over the deltoid and biceps, and there was no reflex contraction of muscular fibre under the electrical stimulus.

The conductors were now shifted to the primary wire, and two moist conductors were employed. The one from the negative pole was placed beneath the spinous process of the scapula, and the conductor from the positive pole was placed upon the muscle to be stimulated.

On passing the current through the deltoid, faint contractions were discovered in the anterior and posterior fibres, but none whatever in the middle fibres; the biceps

contracted feebly; all the other muscles were in tolerable order.

**TREATMENT.**—A Pulvermacher band was applied, direct current positive pole on the spine, then wound round the deltoid, and the negative pole placed on the lower part of the biceps, and retained in position by an elastic bandage, to be worn night and day; excited once a-day with one part vinegar, and eight parts water. Daily, for half-an-hour, each muscular fibre of the paralyzed muscles to be excited with the inverse current of the primary wire of the electro-magnetic battery.

This treatment, without change, was carried on daily for three weeks, with immediate benefit from the first application, and on the 18th of April, I took Mr. G. to Sir William Fergusson completely cured, enabled to use the deltoid and biceps perfectly.

This is a model case. I have had numerous, somewhat similar ones, but it must be borne in mind that the longer the paralysis has lasted, and the more the muscle has wasted, the longer the treatment will be required before a cure can be effected.

Paralysis of the leg, following sciatica, is not uncommon; the treatment is precisely similar, and the result equally satisfactory. I propose in my next paper describing such a case.

MEDICAL SOCIETY  
OF THE  
COLLEGE OF PHYSICIANS OF IRELAND.

The President, Professor STOKES, in the Chair.

At the Meeting of the Medical Society on the evening of Friday the 24th May,

Dr. HERBERT said he was present in consequence of a request conveyed to him by Dr. Guinness, to report some cases of black death alleged to have occurred in the 5th Regiment, during the service of its late surgeon, Dr. Barclay, who had joined the 54th Regiment. He regretted to say that he knew nothing whatever of the cases alleged to have occurred in that regiment. He had heard of some cases of fever which assumed the encephaloid form, accompanied by spots of typhus fever, but these were not cases of black death—at least, he did not so consider them. There had been no official report of the cases, but he had written to Dr. Barclay on the subject, and had not yet received an answer. There was one case of black death under treatment in the Hospital of the 5th Regiment. This case occurred during his absence, and he had received the notes of the case taken by Dr. Skene. The soldier, who had been previously a healthy man, was admitted to hospital, complaining of headache and rigors. Some time after admission he vomited. His pulse was at first very frequent, amounting to 130 or 140 beats in a minute. The extremities were cold; his tongue was cold, and clayey white at the edges, and a dusky brown in the centre. He complained of great thirst, and pain in the head. About eighteen or twenty hours after admission, he complained of intense pain in the right eyeball; symptoms of eritis took place; it was treated with soda water and milk, and a mustard blister was applied to the epigastrium. There were symptoms of encephalitis, and twenty-four hours after admission, spots of the size of a sixpenny piece appeared over his body, and in a few hours increased to the size of a shilling, and in three or four hours afterwards, to the size of half-a-crown. He was treated with stimulants—beef-tea enemata, &c., and was reported by Dr. Skene to be progressing well. Since Dr. Skene had gone on leave of absence, mortification of both feet had set in—one patch, as large as an ordinary lozenge box, being over the ball of the right toe, and on the opposite foot there was a mortified patch under the ball of the little toe, about the size of half-a-crown. These spots of superficial mortification had been rubbed with a stimulating embrocation, and the whole depth of the integuments had sloughed away.

Dr. LAW said he desired to bring under the notice of the Society some cases of what was called cerebro-spinal meningitis. The peculiar phenomena were, remarkable prostration of strength, with violent pain of the head, and pain proceeding in the direction of the nerves of the spine across the body, a sense of constriction extending down the arms and legs, reminding him strongly of the complaints that were made by the patients in the fever of 1848, an aggravation of those symptoms that the French call *malaise*, fidgetiness, and the patients commonly complained of pains in the bones. He brought forward a group of ten cases before the Association, and he mentioned at the time that he had no opportunity, inasmuch as there was no fatal case of ascertaining what the lesion was. At that time he proposed the question, what was the real pathology of this disease? Was it essentially an affection of the spinal system, or was it to be looked on as involving the nervous system? In the end of last June a case was brought into Sir Patrick Dun's Hospital. It was a young female aged 12 years. She had been bathing the day before, and gone to bed perfectly well, but awoke in the night screaming with violent pain of the head and sickness of the stomach. The pain in the head and sickness of stomach, and vomiting continued until she was brought into the hospital at four o'clock on the next day. She was then in a state of complete collapse, the pulse scarcely to be felt, the body perfectly livid, a deep blue stained colour with a remarkable eruption especially on the left leg. There were spots, maculae varying in size. First of all there was a general dark colour of the whole body, and then there were patches of ecchymosis along the limbs with elevated spots, and a remarkable tubercle on one leg. The vomiting continued for some time; she had remarkable hyperaesthesia, extreme restlessness, could scarcely be kept in bed, worked strongly in convulsions, and especially on the left side. However, the convulsions were choreac movements rather than epileptic convulsions. The only thing that could be done was to sustain her as best they could. Everything which they gave her was rejected, and enemata of brandy and beef-tea were the only means by which her strength could be sustained. They applied belladonna down the back, and as soon as she could swallow she got pills consisting of mercury, quinine, and extract of belladonna. The giving of belladonna in this case was suggested by an interesting case of Dr. Byrne's where it was found most effective in relieving tetanus, and he (Dr. Law) was astonished to see how greatly the convulsions ceased on taking it for a short time. On the second day of illness the head of the girl was violently retracted, she complained of a most agonizing pain in the head, especially over the occiput. A blister was applied here, and afforded her a little relief, but not much. On the fifth day after admission she complained of the most violent aggravation of the headache, and this was shortly followed by copious epistaxis, and from that time forward her head was completely relieved. They gave her mercurials, the mouth was slightly affected, and on the seventh day she began to improve, and accordingly as she improved the eruption on the extremities began to fade, and on the fourteenth day she was pronounced convalescent. The head was still retracted, producing a peculiar appearance. No matter in what direction she placed herself the head was rigidly fixed, and the muscles would not admit of any motion. The case went on, she improved up to the end of the month, when he lost sight of her. She then became Dr. H. Kennedy's patient, and he told him that when she came under his care she had sickness of the stomach. He was surprised to hear that the child had relapsed, and on inquiry was told by the nurse that she had taken something which disagreed with her. Now, he (Dr. Law) thought this was a connecting link between these extraordinary cases that occurred as the first epidemic, and those that afterwards appeared and were called the black death. It was better that that name should be given up. He thought it an unfortunate name, for it led people to expect that this disease would be something like the plague. He should mention

that a case similar exactly to the one he spoke of had come under the observation of Dr. Byrne, with this exception, that his case was of a worse type, for the patient died. Dr. Byrne thought it at first a case of cholera, and he (Dr. Law) should have thought so too, although they had not the sunken eye and whispering voice of cholera. Many of these cases of cerebro-spinal arachnitis were mistaken for cholera, and it was a remarkable fact that it had always followed in the wake of cholera.

Dr. AQUILLA SMITH observed that some of the gentlemen who had communicated cases of this disease had spoken of it as "black death." The members of the profession generally were well aware of the great alarm which had been caused in the city in consequence of this name having been given to this form of fever; and it appeared to him desirable that there should be some expression of opinion on the part of the Society to repudiate the term "black death" as a name for this disease. Every one knew that the black death of the middle ages was a true bubo plague, and had no similarity to the form of disease which they were now considering. He was very glad that Dr. Lyons had pleaded guilty to having given the disease a very bad name. It would be in the recollection of the meeting that Dr. Lyons suggested that it should be called "black fever." He objected to that name also—the word "black" being calculated to cause much unnecessary alarm. From what he had heard of the nature of the disease, he should be inclined to term it malignant petechial fever.

The PRESIDENT said the meeting was indebted to Dr. Smith for his observations. The term black death was an improper term. The black death of the middle ages was nothing but the plague of the Levant that had spread over Europe. Dr. Lyons had given up that name, and he was quite sure it would be the feeling of the meeting that the name should be forgotten. It was not very easy to invent a name for this disease. It was his intention in the concluding observations which he would make that evening, to propose the name of "malignant purpuric fever." Still, no doubt, it was a special and most peculiar disease, and a disease which, although it had been observed in other countries, and long observed in America, was, so far as he could see, new to this country.

Dr. DARBY said he had been looking into Hecker, and he thought there were some grounds for justifying Dr. Lyons on the first blush of the moment, in giving the disease the name which was now objected to. He thought there was something very analogous to the cases they were now discussing, related in Hecker—the vomiting, bleeding, and head symptoms were all described, and there was no very remote difference between them, except in the absence, in this disease, of the buboes. There were black spots, discharges of blood, and head symptoms common to both. He wished to bring under their notice, two cases which came under his observation. A girl, fifteen years of age, was sent into his hospital from Kingstown, on the 22nd of March. Her head was thrown back; she had spots on the skin; grinding of the teeth, and convulsions. She died in four or five weeks after admission. He made a post-mortem examination, and found lymph in the pons varolii, and congestion of the membranes of the spine. The spots which were on the body, faded away, and, as they disappeared, they assumed that yellow and green appearance exhibited in the disappearance of a common bruise. Death, which occurred in the last week of April, took place apparently from exhaustion. All the time of her illness, the patient had grinding of the teeth and retracted head, and the retraction continued till within two days of her death. What struck him as remarkable in this case was, that the spots faded, becoming green and yellow, and drab-coloured, for some time before she died. He had another case in his own institution, of a boy who was attacked with acute purpura hæmorrhagica. That boy recovered, and the spots on his body pursued the same course as in the case of the girl, assuming different shades of colour, and gradually disappearing. It struck him that there must be some pecu-

liar epidemic character in this disease, for he had heard of several friends of his having lately seen cases of purpura, which was not a disease met with every day. One of the cases which he had mentioned, certainly had spinal arachnitis.

Dr. LAW said he desired to propound the question. What is to be regarded as the real pathology of this disease? From what he had seen himself, and from what he had heard, he confessed he looked upon it, no matter how modified, as cerebro-spinal arachnitis. The very interesting details which they had had from several members, and especially those presented by Dr. Haverty, confirmed him in this opinion. Every one of the cases mentioned by Dr. Haverty, exhibited distinct signs of inflammation of the membranes of the base of the brain. If the pathology of the disease did not consist there, what was it? Was it a modification of fever? If it were, it was unlike any fever they had ever seen or known in this country. They had never known or met with a case of fever terminating fatally in sixteen hours, and perhaps there was no place where they had unfortunately a better opportunity of seeing fever in all its modifications, than in this country. They had never seen anything of this kind in fever, nor had they seen fever complicated with this affection of the spinal membrane. On the contrary, most persons who had directed their attention to affections of the nervous system, had observed the appearance of eruptions in such cases. He alluded especially to Dr. Hanfield Jones who, in his Lumleian work on diseases of the nervous system, observed how frequently these eruptions on the skin are found to be associated with purely nervous affections. He alluded to a case in which a person presented on the skin an eruption like bad scarlatina; and in other cases it was not an unfrequent thing with surgeons in operations, to observe these eruptions on the skin, resembling the purple spots in the disease now under consideration, and which took place when there seemed to be no other lesion than the shock of the muscular system. They all knew how nervous impressions led to this kind of bleeding—extensive purpura, with bleeding from the gums. They might recall a case of a gentleman who died from bleeding, caused by mental impressions, and where these large purple patches presented themselves before death. Every case that had yet been brought forward, exhibited marks of inflammation of the membranes of the brain, and, therefore, he thought they were warranted in supposing that there was an intimate relation between this disease and cerebro-spinal arachnitis. There was, certainly, no fever ever yet met with in this country, at least, that had exhibited this peculiar condition of the nervous system. If there be any modification of fever to which this disease could be referred, it was not any fever with which we were familiar, but it might be the intermittent fever which occurred in other countries.

Dr. QUINLAN thought the expression "black death" was not a bad one, as descriptive of the peculiar feature of the disease. The black death which devastated Europe in the middle ages was the plague of the East which existed at the present day, and came over to England in consequence of the low sanitary condition in which England then was. He believed that when the plague invaded England on that occasion, this country had the same fortunate exemption from it which it had from the rinderpest last year. He thought the expression black fever, if it did not express the very nature of the disease, was not altogether inappropriate.

Dr. AQUILLA SMITH, in reference to the statement made by Dr. Quinlan, that the "Black Death" had not reached Ireland, directed the attention of the meeting to the brief account of the pestilence given in Clyn's "Annals of Ireland," published by the Irish Archæological Society in 1849, which is of great historical value on account of the very scanty information given in Hecker's admirable history of the "Black Death," respecting the progress of the pestilence in Ireland, which is composed in the following words: "Ireland was much less heavily visited than England. The

disease seems to have scarcely reached the mountainous districts of that kingdom."

Clyn's account of the "Black Death" in Ireland:—

"Item, hoc anno [1348] et maxime mense Septembri et Octobri convenerunt undique de diversis partibus Hiberniæ, episcopi et prelati, viri ecclesiastici et religiosi, magnates et alii, et communiter omnes utriusque sexus ad peregrinationem et vadacionem aque de Thaht-Molingis (St. Moling's, Co. Carlow) turmatim et in multitudine, sic ut multa milia hominum simul illuc multis diebus convenire videres, quidam venerunt devocionis affectu, alii (sed plures) pestilencie metu, que tunc nimis invaluit, que primo juxta Dubliniam apud Howht [Dalkey—in *marginem*] et Droghda [Drogheda] incepit, ipsas civitates Dubliniam et Droghda fere destruxit et vastavit incolis et hominibus. Ita ut in Dublinia tantum, a principio Augusti usque nativitatem Domini xiiij. millia hominum mortui sunt. Ista pestilencia sic erat contagiosa quod tangentes mortuos vel inde infirmos incontinerenter et inficiebantur et moriebantur, et confitens et confessor simul ducerentur ad sepulchrum. Et pre timore et horrore, pietatis opera et misericordie, videlicet, visitare infirmos et mortuos sepellire, homines exercere vix audebant. Nam multi ex antraxe et ex apostematibus, et pustulis que creverunt in tibiis et sub asellis (axillis), alii ex passione capitis et quasi in frenesim versi, alii spuendo sanguinem moriebantur. In conventu Minorum de Drouda xxv. et in Dublinia apud eosdem xxiiij. fratres mortui sunt, ante usque Natale. Ista pestilencia apud Kilkenniam in xl<sup>o</sup>. [*i.e.*—Lent] invaluit, nam vi<sup>o</sup> die Marci viij. Fratres Predicatores infra diem Natate obierunt, vix in domo unus tantum moriebatur, sed communiter vir et uxor cum natis eorum et familia unam vian, scilicet mortis, transierunt. Ego autem frater Johannes Clyn de ordine Minorum et conventu Kilkennie hec notabilia facta, que tempore meo acciderunt, in hoc libro scripsi, que oulata fide vel fide digno relatu didici, et ne gesta notabilia cum tempore perirent et a memoria recederent futurorum, videns hec multa mala et mundum totum quasi in maligno positum, inter mortuos mortem exputans donec venial, sicut veranter andivi et examinaui sic in scripturam redegi, et ne scriptura cum scriptore pereat, et opus simul cum operario deficiat, dimitto pergamenam pro opere contimando, si forte in futuro homo superstes remaneat, an aliquis de genere Ade hanc pestilenciam possit evadere et opus continnare inceptum."

Dr. M'SWINEY said the valuable observations which had fallen on that and on the previous night from the different gentlemen who had brought forward cases would appear to him to clearly point out that within the last twelve or eighteen months there had been a number of cases of cerebro-spinal arachnitis, of the most fatal character, in Dublin; and, secondly, that there had been a malady which had been characterized by some competent observers as quite new, and the like of which they had never witnessed or even read of before. This latter malady was characterized by an extreme fatality, by the suddenness with which it occurred, and by a remarkable eruption, the nature of which was under consideration. The two cases which came under his observation rather rapidly served to illustrate in the most typical manner these two forms of disease. They were both cases recorded in the proceedings of the Pathological Society, one having been brought forward in the month of January, and the other in February last. One case of cerebro-spinal arachnitis, the subject of it being a little boy, was instantaneous in its invasion. There were no premonitory symptoms. He fell into convulsions, was severely tetanized, and died, without once regaining consciousness, in the seventeenth hour of his illness. The brain and spinal cord bore well-marked evidence of intense congestion. There was probably no time for the effusion of lymph, and the most remarkable pathological circumstance was that an inch and a-half of the spinal cord had undergone the most complete softening, and was broken up so as to resemble cream. This boy was unspotted, and the case was

regarded as one of spinal meningitis. In a week afterwards, a case most rapidly fatal occurred. It was that of a little girl, who was first seized by illness at eight o'clock in the morning—the first illness being marked by rigor, followed by nausea and then vomiting. The mother exhibited drinks from eight o'clock until eleven, each drink being thrown off almost immediately. At eleven o'clock purple spots were noticed on the child's face, and the mother, becoming alarmed, then took advice. At three o'clock the child was dead—four hours after the purple spots manifested themselves, and eleven hours after the vomiting commenced. The brain and spinal cord were examined at the Pathological Society, and no pathological evidence of any lesion, save the single one of the diffusion of small spots of blood in the brain, was discovered in the child's body. What the decision of the Society would be as to the connection or non-connection of these cases, he could not, of course, anticipate. He was, however, of opinion that they were distinct diseases. He heard with some pleasure the recommendation to abolish that most inexpressive name which the disease had received, the more so as, at the meeting of the Pathological Society at which he brought forward the case, he for the first time proposed that something like a scientific nomenclature should be adopted. He stated that he knew of no disease which it resembled so much as purpura, and he proposed that it should be called malignant purpuric exanthem or malignant purpura. It might be within the knowledge of men who had extensive practice that there were threatenings at present of an epidemic of purpura. In the hospital which he was attached to, cases with purpuric symptoms were not rare. He had himself under his care, in an institution four miles from town, two ladies, sisters, of advanced age, who had large patches of purpura on their extremities, some black, some red, and some green, as the blood was dying away. In this case the disease was certainly not due to an insufficiency of food. Dr. Lyons, as they all knew, was under the impression that attacks of disease such as this purpuric fever, preceded great and wide-spread epidemics such as cholera.

Dr. BENNETT rose to bring forward a case which had occurred in Sir Patrick Dun's Hospital, presenting a complication of pericarditis, with symptoms of cerebro-spinal arachnitis, and the eruption of the present epidemic. The facts of the case were as follows:—

A little girl, 5 years of age, was admitted into Sir P. Dun's Hospital on the morning of 15th March, having been ill for the three previous days. She lay with the head retracted, and the spinal muscles were rigid, the legs and arms were flexed, but not rigidly. She complained of intense pain in the head, and placed her hand on the forehead when asked where the pain was; her cheeks were flushed; the tongue was readily protruded, and was coated with a thick grey fur; the respiration was very irregular; some small spots which did not disappear on pressure were scattered over the arms and legs, a few were on the trunk, and one, the largest and most recently formed, was seated on the left eyelid. These spots were the same as those observed in the greater number of the cases of the present epidemic, and were blood extravasations, some of them being raised above the surface, others ordinary petechiae. The child suffered much from thirst, and swallowed water greedily. She was very watchful, and suffered much from intolerance of light, her eyes were bright, and her pupils much contracted; her pulse was hurried, small and weak, but regular; the heart's action was strong and jerking; a loud and continuous murmur was heard all over the cardiac region, and was prolonged into the great vessels. On the sixth day a pericardial friction murmur was audible with the first sound, and a few days later facial paralysis of the left side occurred, while the tongue deviated slightly to the right. There was at this time a remarkable blush on the paralysed side of the face, while the opposite side was quite pale. The spots faded in a few days without any fresh crop appearing. The case went through a series of alterations until it seemed almost certain that death was immi-

nent, and at one time the temperature was 95. Finally, after this the case had rallied, and had gone on to convalescence, with a diminution of the facial paralysis. He thought that the symptoms of this case warranted him in bringing it forward, as being referrible to the present epidemic, and he thought also the occurrence of facial paralysis, and also paralysis of the tongue, and the peculiar aspect of the face, exclusive of the more general symptoms, were very strong evidence that if the case had ended fatally they would have found the evidence of inflammation of the brain and cord. He brought the case forward for two reasons—first, as it presents the complication of cardiac inflammation, which, as far as he knew, had been observed in but one other instance during the present epidemic; and, secondly, as he believed that the case threw much light on cases recorded both by Dr. Mayne and Dr. Graves. In Dr. Mayne's case, which he published in the proceedings of the Pathological Society, a similar group of symptoms occurred, but no eruption. He being at the time engaged with cases of the former epidemic, recognised the case, and set it down as meningitis. After death the heart, which had not been examined during life, was found inflamed, and the brain and cord free from inflammation. Dr. Mayne published the case to warn others against what he thought was an error, and seems to have referred the symptoms in his case entirely to reflex irritation, due to the pericarditis. He (Dr. Bennett) thought it highly probable that Dr. Mayne's case was one of those that had been met with in the present epidemic, where, though the symptoms of inflammation of the brain and cord were present, the post-mortem evidence was wanting, and in which it became necessary to attribute the symptoms to the action of a specific poison. Dr. Graves published a case in one of his lectures which presented most of the symptoms of the present epidemic, and in addition, a murmur, or rather murmurs, in the cardiac region of nearly identical character with the present case. Dr. Graves concludes that the case was entirely due to anæmia. He (Dr. Bennett) was strongly inclined to regard it as identical with this case in every way—at least such an explanation was more evident than Dr. Graves'. He thought the consideration of these cases must lead them to conclude that the cerebro-spinal meningitis, while it was the most frequent pathological result of the specific poison of this epidemic was not the necessary one. They must refer all the cases to one cause not for the first time acting, not different absolutely from the poison of 1846, but varying from it in its greater tendency to produce cutaneous eruptions as one of the earliest results of its action.

Dr. GRIMSHAW desired to mention a case which he thought was of some interest. It presented a feature which was observed in one of Dr. Hughes's cases—namely, a vesicular eruption over a portion of the body. It had no symptoms whatever of cerebro-spinal arachnitis. The disease only lasted eight days. The patient was a woman of 32 years of age, was married, and had had several children. She was admitted into hospital under the care of Dr. Kennedy, was then transferred to him (Dr. Grimshaw), and afterwards to Dr. Moore, who had sent the case back to him. On admission to hospital the patient presented a very remarkable appearance; her face was covered with vesicles somewhat resembling small-pox. These vesicles were surrounded with inflamed areola. In some the appearance was as if a black line had been drawn round the vesicle and "smudged off" over the surrounding skin. The fingers of both hands were quite black and covered with large bullæ, moveable under the cuticle as in cases of commencing gangrene. There were a large number of vesicles on the upper part of the right arm, and on the left arm. All over the lower part of the abdomen, the sacral regions and nates, the vesicles were very numerous and much darker than elsewhere, giving the whole of these parts of the body almost a black appearance. On the lower extremities there were scarcely any vesicles, but the feet were black and swollen, and an old ulcer on the right leg had put on a gangrenous appearance, large sloughs

having formed around it for the space of a couple of inches. She presented no symptoms of arachnitis. The temperature at the time of admission was 105; it fell to 99, and on the day of her death rose to 101. The immediate cause of her death seemed to be the extension of her disease to the mucous membranes. She complained of soreness of the mouth and throat, and difficulty of swallowing; and on examination the mucous membranes of the mouth and fauces seemed ulcerated, and detached in many places. The chest became engaged, the whole of the lungs filled with bronchitis, and the immediate cause of death seemed to be the bronchitis. The pulse was at first 140; it fell to 84 on the day before her death, and on that day it was found impossible to count it. The case was considered by all his colleagues to be one of the class which they were now describing. It was stated that she had syphilis ten years ago, for which she received no treatment. The question arose in his mind as to whether this was not purpura, but on looking to the books in which that disease was described he came to the conclusion that it did not bear any resemblance to it.

Dr. GORDON—It seemed quite conceded that the title of black death was not to be used any longer, and also that this disease was not a new one, but in many respects similar to the epidemics which had occurred at various times on the Continent of Europe, and in America. It remained only to settle what the title of this disease was to be. He should think the only true ground to go upon for nomenclature, would be to endeavour to find out what the strict nature of the disease was, and not to define it, or call it by any *symptom* which might arise. From the number of cases that had occurred in which two sets of symptoms, one which was (in his opinion erroneously) supposed to be a lesion of the circulation, the other a lesion of the nervous centres, had been developed so largely, they must, *a priori*, expect that they both had their origin in the same affection. Very few indeed, if any, of these cases which are characterized by one predominant set of symptoms, are altogether deficient in the symptoms of the other form. But, in his opinion, these eruptions were all a symptom of nervous lesion (the sympathetic probably) rather than a direct symptom of lesion of circulation, and many of these cases presented also symptoms of actual pathological changes in the nervous centres. They were not to expect in every case decidedly marked symptoms of disease of the nervous centres, but there had not occurred to him any cases in which one or more symptoms, strictly referrible to the nervous centres, were not present, and whether there was a well-marked retraction of the head, or a dark coloured eruption, the case was equally preceded by nervous disease. Dr. McSwiney was in error in supposing that the cases he referred to was the most rapid on record, or that on account of the shortness of its duration, organic change could not have taken place. He had recorded (see *Dublin Quarterly Journal*, May 1) a case which had lasted not quite five hours, and, on parts of the brain, was found a very thin layer of purulent effusion. From an analysis of a great number of cases (there had been more than thirty in the Hardwicke Hospital, dating back to his first case in April, 1866), he would say, that the two sets of symptoms, as they were termed, must be referred to the one cause, and, therefore, he would be disposed to call the disease *Fever with cerebro-spinal meningitis*. The eruption in these cases differed in many respects from purpura, which, at all events, could be looked upon as only a symptom, and therefore he considered the term "purpuric fever" to be erroneous.

Dr. LITTLE said that in the case which occurred in Trinity College, pleurisy as well as bronchitis came on before death. One of the first questions, as it seemed to him, which they had to decide, was whether this new epidemic was due to local causes or to blood-poisoning. He thought when they found that the serous covering of the heart and lungs are likely to be affected, it appeared to him that they were dealing with poisoning of the blood. In the other case in the College, the eruptions came out symmetrically,

and the symptoms of cerebro-spinal arachnitis were well-marked. Death took place in seventy-two hours, and six or eight hours before death the bronchial affection was first discovered.

Dr. HENRY KENNEDY congratulated the Association on the great mass of valuable information brought before it; and this, he said, was the more important as the present disease was so scattered about that five or six cases might be considered a large experience. Three views of this disease had been advanced—one that it was a malignant spotted fever; a second that its essence was a cerebro-spinal arachnitis; and the third that the two diseases co-existed, the one being superadded, as it were, to the other. He then went on to say:—I myself hold the latter view, having a strong conviction that this is the proper way to consider the question. Before speaking of the disease itself, I would call attention to the fact that when any of the acute affections assume a great malignity, they run their course very much more rapidly than is usual; and, what is very important to bear in mind, present then a series of symptoms wonderfully similar to each other. As examples of what I myself have seen I may mention scarlatina, the disease known as acute jaundice, and our common typhus, when it assumes a very bad form. Some years back I saw many cases of scarlatina which terminated within forty-eight hours—the prominent symptoms being vomiting, purging, stupor, coma, convulsions. With the exception of purging, it was just the same with the cases of acute jaundice, of which I have seen five instances; whilst of cases of the worst typhus, and I have seen it run its course in six days, the symptoms were vomiting, stupor, coma; convulsions very rarely occurring. In this last disease the appearance of the body after death was often very remarkable, the veins having allowed a part of their contents to escape, and there existing, at the same time, general mottling, not distinct petechiæ. But further, when I made an examination of any of these three diseases, I found appearances which were wonderfully similar one to the other; that is, I found violent congestions affecting the brain, extending down the spinal marrow, and attended by more or less serous effusion, which, in the cases of common fever, was often tinged with blood. Now it will be observed that the symptoms during life were in all referrible to the brain and spine, and the appearances after death were, I think I may say identical, and I believe are not to be classed as in any way connected with inflammation. As I go on the meeting will see the bearing of these remarks. It was in 1846 that Dr. Darby, of Bray, first described, in this country, some cases of spinal arachnitis. His remarks were very shortly followed by a paper of the late Dr. Mayne, and neither of these observers say a word about the presence of spots, though they describe the disease with great clearness. Hence, I look upon it as certain that, at that period at least, no spots existed; and it may be mentioned in passing, I myself saw, at the South Workhouse, several of the cases on which Dr. Mayne's paper was founded, and I also saw one case where acute pleuritis was alone found, though the symptoms during life were entirely referrible to the brain and spinal marrow. Since 1846 the disease seems to have disappeared till about two years since, when cases began to appear in the wards of the Cork-street Hospital. These at first were all simple cases of the disease; but though very well-marked they did not present the same intensity of symptoms as in the year 1846; neither was the disease confined to boys, as happened in the first instance. Adults were now attacked, and, in my own wards, more females than males. In a very short time, however, the disease became a complication of our ordinary typhus, and then many of the cases presented the ordinary spots and other signs of typhus, together with well-marked symptoms of spinal arachnitis. In other cases again, the patients came in with typhus, being spotted, and then, in the progress of the case, spinal arachnitis set in. Neither was this last observed in one type of fever alone; and the tendency to the affection was very remarkable. Three young females,

two of them being between twenty and thirty years of age, were attacked with the disease, and nearly at the same time, one of them very severely. The first had had typhoid, from which she was quite convalescent; the second was passing through gastric fever when attacked, her life was in the balance for many days; the third had had common fever, and was up before the spinal arachnitis showed itself. Now it was whilst this state of things was going on that the new and much more terrible disease, which, for the present, and following the great majority of the American writers, I shall call "spotted fever," appeared amongst us. Is it likely, I would ask here, and keeping in mind the facts just stated, that this new affection is but a modification of spinal arachnitis. I cannot think so. We saw that this latter affection first existed *per se*, then became a complication of typhus and other types of fever. Where is the difficulty in supposing that it may also be a complication of the "spotted fever?" This view, and this only, appears to me capable of explaining all the facts known. For, whilst it must be admitted that the great majority of the cases presented the remarkable spots and spinal arachnitis at the same time, it is not to be forgotten that many of the cases which had the spots did not present any symptoms referrible to the brain or spine. One well-marked instance of this was given to-night by Dr. M'Swiney, and of the two cases which came under my own notice, one had no symptoms whatever referrible to either the brain or spine. I know, too, that many similar instances have been met by others; and when such cases have been examined, no trace of inflammatory action has been found in either the brain or spine. For I do not admit that congestion, with some serous effusion—which, it will be recollected, is a state common to any of the acute diseases that run a very rapid course—is due to inflammation. If it be, then the essence of our typhus fever must be inflammation, which I presume few will maintain. Taking, then, all the facts at present known, and more particularly the one that our typhus fever has, within these two years, been frequently complicated by spinal arachnitis, into consideration, it appears to me that no other conclusion can be arrived at than that the late terrible disease which has visited us is a specific fever, and that the spinal arachnitis is but a complication, which may or may not be present. On the treatment of the spinal arachnitis, when it complicates common typhus, I have got the idea that it is not usually as actively treated as it requires. In my own hands I know that antiphlogistics, including local bleeding and mercury, have been followed by the most satisfactory results; and when the disease was seen very early a fatal result was most unusual.

(To be continued.)

#### HARVEIAN SOCIETY OF LONDON—MAY 23.

Dr. J. E. POLLOCK, President.

#### THE PREVENTION OF VENEREAL DISEASE.

At the fifth meeting of the Harveian Society's Committee, the following communications were read:—

Mr. Rooke reports from the *Dreadnought* Seamen's Hospital, that there are a daily number of forty-seven male cases seen there on an average, or about one-third of the surgical patients. No special beds are reserved for venereal cases. "This return chiefly represents the primary affection. Many of the sequelæ of syphilis, such as ulcers, diseases of bones, and internal organs, are not included. If the Contagious Act were extended to the waterside parishes of the chief mercantile ports the advantages to the sailors of the mercantile marine would be incalculable. The history of our patients proves that they are exposed to, and contract disease, immediately on the arrival of their ships in port. The sailors of many ships are picked up by lodging-house keepers, who provide them with beds, liquors, and diseased women, whilst they are waiting to be paid their wages. Consequently, when the sailor goes to the shipping-office to receive his pay, the larger part, if not all, is already pledged to the boarding-house keeper. In a very few days he

applies for admission on board the *Dreadnought*, suffering from syphilis, and often from delirium tremens. The class of women who consort with sailors, are of the lowest order, so that the difficulties of carrying out a systematic inspection would be very little."

Dr. Rogers reports from the Strand Union, an average daily attendance of two males and three female venereal patients, or about ten per cent. of the surgical cases. There are no venereal beds in the workhouse; "we always send our patients to the Lock Hospital."

The report from Whitechapel Workhouse gives an average daily attendance of one male and one female venereal patient. There are ten male and fifteen female venereal beds in the workhouse.

The report from the Poplar Hospital says, that only two or three venereal patients are seen daily. "There are no beds for lock patients, the beds being entirely reserved for accidents."

The report from the City of London Workhouse shows, that there are no beds for venereal patients in the workhouse, and, "perhaps, not four such cases are treated during the whole year."

Mr. Guye reports from the Paddington Workhouse, that "the Guardians subscribe liberally to the Lock Hospital, and not more than a dozen cases come to the Workhouse Infirmary during twelve months, to remain but a day or two in the receiving wards, previous to reception into the Lock. No beds are, therefore, reserved for venereal cases."

The report from St. Olave's Workhouse gives a daily average of five female patients, or one in forty of the surgical cases seen. There are three beds for males, and five for female venereal patients.

Dr. Bullen reports from the Lambeth Workhouse, that there are about two a-week of in-patients' venereal cases during the year. "I have had from eleven to twelve cases of females in a ward at one time."

Dr. Clark reports from Shoreditch Workhouse, that syphilitic patients are sent from thence to the Lock Hospital. That "we treat somewhere about thirty patients yearly with gonorrhœa, and the sequelæ of syphilis. We have no beds for venereal patients."

Dr. Skegg reports from St. Martin's Workhouse, that there is a daily average of two male and three female venereal patients seen there, or one in thirty of the surgical patients. "No special number of beds for Lock cases."

The report from Hackney Workhouse gives a daily average of two males and three female venereal patients. There are four beds for males and five for female venereal cases.

Dr. Smart reports from Bethnal Green Workhouse, "the number of cases which come under my notice is very small at present. I have only one case of gonorrhœa, and about six cases of secondary syphilis. I do not suppose I get more than twenty cases during the year. I have no beds set apart for such cases."

Mr. Harris reports from St. Luke's Workhouse that there are no venereal patients seen there—no venereal beds in the hospital. "Under the Poor-law, venereal cases, as such, are not received. Destitution is the plea. No venereal disease is seen by me, as Medical Officer, except occasional broken-down constitutions under secondary and tertiary syphilis."

Dr. William Bennett reports from St. Giles's Workhouse that "there are scarcely any venereal out-patients. The few who apply to be admitted are nearly always females, and they are sent to the Lock Hospital, with the exception of an occasional case of secondary syphilis."

Dr. Williams reports from the Hospital for Sick Children, Great Ormond-street, that the number of syphilitic children treated during the year 1866 was 93 males and 105 females; or in the proportion of 1 to 7 and 1 to 4 of the surgical patients seen during the year. "There are no beds set apart for such cases, although syphilitic children are, of course, admitted."

Dr. Smith reports from Notting-hill Dispensary that there is a daily average of 5 males and 3 females, or about 1 in 8 of the cases venereal. No beds.

Mr. Hunt reports from the Western Dispensary for Diseases of the Skin, that there are no in-patients. "It is rare that a case of primary syphilis appears for treatment; but the secondary and tertiary forms are very common. During the last 40 days about 800 patients have been under treatment; of these, about 100 were syphilitic, nearly equally divided among males and females, and comprising young infants, a small proportion. Very few prostitutes ever attend here."

Mr. Lewis reports from the Western Ophthalmic Hospital,

that "out of 2040 cases treated during the past year, 11 are described as syphilitic."

Mr. Hulme reports from the Central London Ophthalmic Hospital, that of 2000 cases seen annually by him, or 40 a-week—of these 40, about 7 are venereal iritis or keratitis.

Dr. DRYSDALE said that Mr. Jonathan Hutchinson's report to the Venereal Committee showed that out of 65 patients seen by him on one morning at the Ophthalmic Hospital, Moorfields, 13 were venereal cases, or 1 in 5.

The PRESIDENT remarked on the fact that the workhouses seemed to send all their venereal patients away. Would Mr. Lane explain how they managed at the Lock?

Mr. LANE said that the Governors of the Lock had the privilege, as usual, on subscribing five guineas, of sending a certain number of patients there annually. The workhouses, therefore, subscribed 10, 20, or even more guineas annually, and sent their venereal cases there. If they did their best in the Lock, they had never more than 30 beds for such cases, and were obliged constantly to send them away. The rest of the beds in the Lock Hospital were for Government cases.

Mr. CURGENVEN said that he had observed that at the Royal Free Hospital, the worst cases were sent there from the workhouses.

Mr. LANE said that provision should be made in Mr. Hardy's Act, now before Parliament, for the admission of venereal cases into workhouse hospitals.

Dr. TILBURY FOX stated that Mr. Hardy's Act was already in operation.

The following motion was made by Dr. CHARLES DRYSDALE, seconded by Mr. JAMES LANE, and carried unanimously:—

"That this Committee (considering the vast amount of preventible venereal disease existing in London, and also the fact that destitute women, when suffering from such diseases, are not admitted into the workhouse infirmaries, but, in the majority of cases, sent to the Lock Hospital, which is quite inadequate for their reception) are of opinion that immediate provision should be made for the reception of destitute persons suffering from this disease, either in special hospitals, or in special wards, set apart for such cases in the workhouse infirmaries; and they would earnestly recommend that provision should be made for this purpose on the carrying out of Mr. Hardy's Bill."

Mr. JAMES LANE said that now was the time to secure such provision. Diseased prostitutes were at present obliged to go on with their trade, in order to live.

Mr. CURGENVEN said that there was to be a general rate over the whole of London for the maintenance of the hospitals under Mr. Hardy's Act.

Dr. BEIGEL said that prostitutes are liable in Prussia to imprisonment for five months, and, if foreigners, may be banished. Procurers, also, are liable to imprisonment for a time not less than six months, with hard labour. According to the old law, punishment was awarded to women for infecting men, with hard labour, for a period of years. Unqualified persons are fined if they attempt to cure syphilis. Dr. Beigel also added that the enlargement of accommodation in Prussia had much lessened diseases, whilst the registration of women had not seemed to him of much use in Berlin towards that end.

Dr. C. DRYSDALE said that Mr. Cutler, in his evidence before the Venereal Diseases' Committee, had shown that in the Prussian camp, with 20,000 men, there were only in 1865, seven men and four women diseased, whilst at Aldershot nearly half the men were diseased.

The PRESIDENT asked Dr. Stuart, of Woolwich, who has the charge of the inspection of prostitutes in that town, to be so kind as to give the Committee some information as to the effects of his inspection.

Dr. STUART, of Woolwich, said that the action of the Contagious Diseases' Act, 1866, had been most salutary as far as Woolwich was concerned. In October, 1866, the proportion of venereal cases to the number of troops stationed there was as 1.75 per cent. of the number. In April, 1867, this had decreased to .5 per cent. At first the women who were examined were very frequently and gravely diseased; but latterly disease was much less frequent, and milder in type. There was no registration for the women, so that as yet the examinations had only extended to the lowest classes of them. These were by no means averse to being examined. When diseased the girls were sent to the Lock Hospital. The examinations were conducted in a small house adjoining to his own private residence.

Mr. JAMES LANE said that there was a remarkable contrast

between the cases now sent from Woolwich and those which formerly came from it, and there was an equally striking contrast between the cases sent from workhouses and by the Government now; the latter being so much milder.

It was proposed by Mr. JAMES LANE seconded by Dr. TILBURY FOX, and carried by the meeting, "That this Committee is of opinion that the clauses contained in the Contagious Diseases' Act, 1866, might, with some slight and obvious alterations, be adopted in the carrying out of the regulations formerly proposed by Mr. Lane, and accepted by the Committee."

Dr. VINTRAS said that venereal cases ought to be admitted into ordinary hospitals. He did not think the Governors would care what class of cases were taken in.

Dr. BEIGEL said that at the Metropolitan Free Hospital the Governors paid their money and never troubled themselves with the class of cases.

Dr. DRYSDALE said that this was only the case in the more liberal and generous hospitals. It was quite different in many others.

Mr. CURGENVEN said that, if the ordinary run of Governors knew that venereal diseases were treated in a hospital, they would no longer subscribe, and Guy's and Bartholomew's had large private funds, which accounted for their venereal beds.

Mr. LANE said that it should not be left to the mercy of Governors whether this class of cases should be treated or not, and therefore Government or parish funds should be used for the purpose of providing accommodation for female venereal patients.

It was arranged that a sub-committee be formed to write a report and present it to the committee at an early date, and that a general meeting of the Profession should be held at the latter end of June, when the presence of several members of Parliament, such as Mr. Hardy and others should be solicited, and that an effort should be made to effect some early legislation upon this important question.

The PRESIDENT asked Dr. Yandell, of Louisville, Kentucky, if venereal diseases were prevalent in America, and if there was any police registrations.

Dr. YANDELL replied that these diseases were very prevalent; but that there was no provision for preventing them. Dr. Sanger had been lately asked to report to Congress, and he believed that there was a bill before Congress this very year to remedy the evil.

Dr. DRYSDALE said that recently a letter from Mr. B. Hill had appeared in the *British Medical Journal*, censuring the practice of some gentlemen, who had acted as medical officers to private brothels. As he thought the subject important he would mention, that two much respected members of the Harveian Committee, Dr. De Meric and Dr. A. Vintras, had given public evidence before the Venereal Diseases' Committee, of which Mr. Skey was president, as to having so inspected some houses of that kind. Now, he could quite understand the views of an eminent surgeon, Mr. Solly, who gave evidence in the Committee, that he thought that venereal diseases were, "intended as a punishment for our sins, and that we should not interfere in the matter." Such views were clear and definite, and belonged to what had been styled the *a priori* school of ethics; but Mr. Hill was apparently in favour of preventing venereal disease, and, yet, he objected to Dr. De Meric for thus preventing it. He (Dr. Drysdale), adopting as he did the utilitarian standard of ethics, must say, that he thought the function of a medical man was to cure and prevent disease, and certainly as long as Government so utterly neglected their part in this question, as in this country and America, he thought it rather meritorious than blameable in individuals to supply voluntarily the omission. As to questions of receiving emolument, that was merely an accident in medical questions. The primary question was to get work done; and, of course, it was not so likely to be done efficiently by gentlemen of independent incomes, as by those who were paid for the work done.

Dr. CHAPMAN thought that the views held by Mr. Solly and Mr. Hill were opposed to all prevention of any disease which persons brought on by carelessness and bad habits, and was of the ascetic or puritanical school of arguments. Utility or the greatest happiness principle required the prevention and cure of all diseases as such.

Dr. STUART, of Woolwich, said that several articles had already appeared in the local Woolwich papers censuring the examination of prostitutes, and objecting to their being brought into a decent street, like that in which he resided. The girls, too, sometimes pretended to be menstruating, in order to avoid examination, although they were not in that state.

## THE ST. ANDREWS GRADUATES' ASSOCIATION.

THIS body has been formally reconstituted after having been for some time in abeyance. The immediate cause of its sudden revival is the injustice with which the Medical Graduates of this ancient University are threatened by the new Scotch Reform Bill, and on which we have commented in our leading columns. As soon as the bill was printed, and the design of its framers became manifest, those who had been active in the old Association of St. Andrews Graduates, felt that the time for renewed effort had arrived. A meeting was called last Wednesday afternoon, at the house of Dr. Richardson, to consider whether any, and if so, what steps should be taken in the matter—the result being the reconstitution, with an enlarged basis of the old St. Andrews Graduates' Association, as will be seen from the subjoined report of the proceedings:—

Dr. RICHARDSON having been called to the chair, said that he and some other friends had called the meeting because they felt that the University was in danger of losing both its prestige and its rights, and that a great insult was offered to its medical graduates. He observed that the old St. Andrews Association had taken very active steps in the matter of Medical Reform, and partly through its exertions was to be attributed the fact that the University still enjoyed certain privileges. He gave a history of its efforts respecting Mr. Headlam's bill, then as to Mr. Cowper's, afterwards of the "Medical Act," which became law, and finally of its having succeeded in enforcing the rights of these graduates to office under the Poor-law. Since then the Association had not met. It has, in fact, been dormant, but he felt the time had come to resuscitate it. He would name that, so far as he could make out, there were about 3000 Medical Graduates of the University practising at the present time. These men had paid to Government about £45,000 for stamp-duty alone. But the Government Bill proposes to deprive them all of the franchise, except those who have passed since 1863, and which he believed would not exceed 36 in number. All these men had passed severe examinations before receiving their degrees; many of them held other diplomas, and there was not a shadow of reason for depriving them of their just rights. For his part he would be glad to see a deputation at once wait upon one of the Ministers, and place the simple facts before him. He had no doubt, whatever, that the public would recognise the claims of the graduates. He would, therefore, call upon those who were prepared to propose distinct resolutions.

The utmost unanimity prevailed in the meeting, so that it is unnecessary to report the speeches made, each of which offered some practical suggestions. The resolutions were carried unanimously, as follows:—

Dr. ROGERS proposed, Dr. PROSSER JAMES seconded—"That an Association to be called the 'St. Andrews Graduates' Association,' be constituted."

Dr. Collinson spoke.

Carried unanimously.

Dr. DRYSDALE proposed, Dr. DUDFIELD seconded—"That Dr. Richardson be president; Dr. Paul, hon. treasurer; Dr. Sedgwick, hon. secretary."

Professor Macdonald and Dr. Griffith spoke.

Dr. WYNN WILLIAMS proposed, Dr. GRIFFITH seconded—"That all graduates of the University of St. Andrews be admitted to the Association on forwarding their names to the Hon. Secretary, Dr. Sedgwick, 2, Gloucester-terrace, Hyde Park, W., and on payment of 5s. annually for expenses."

Professor Macdonald and Dr. Rogers spoke.

Dr. BALLARD proposed, Dr. PAUL seconded—"That this Association use every endeavour to secure the enfranchisement of all Medical Graduates of the University of St. Andrews."

"That a deputation be formed to wait upon the Chancellor of the Exchequer to represent to him the views of the Graduates, and of their claims to full enfranchisement."—Proposed by Dr. D. DAVIES, seconded by Dr. POWELL.

Dr. ROGERS proposed, Dr. DUDFIELD seconded—"That advertisements be inserted in the medical periodicals, announcing briefly the constitution of the Association, and that a circular letter to the same effect be sent to all the Medical Graduates of the University in the United Kingdom."

Letters of approval, &c., read from Dr. Greenhalgh, Dr. Tanner, Dr. Thesleton Dyer, Dr. Whitmore, and others.

The following graduates were present at the meeting:—Drs. Ballard, Richardson, Wynn Williams, Ray, J. Rogers, Drysdale, Prosser James, Macdonald, Powell, Dudfield, Collinson,

David Davies, Paul, Sedgwick, Griffith, Seaton, and Day Goss.

Since the meeting, a letter has been sent to the graduates, according to the resolution, from which we extract the following:—

"On previous occasions it has been found necessary to arrange for meetings of the graduates in London to consider matters materially affecting the status of the University, and those meetings have been of much service. On the present occasion the same necessity for action has arisen, owing to the provisions of the new Scotch Reform Act. In this Bill it is provided that there shall be one representative in Parliament for the conjoined Universities of Edinburgh and St. Andrews; but by clause 30, no doctors of medicine except those 'on whom that degree has been conferred subsequent to January 1, 1863,' and those in previous years who have attended in the University 'two or more classes qualifying for such Degree,' are entitled to vote in the election of a Member of Parliament for the Universities. The clause, as it virtually excludes the whole body of Medical Graduates of St. Andrews from the franchise, is too obviously unjust to be allowed to pass without opposition, and the Association has for its primary and immediate object the establishment of the rights of all graduates who have undergone an examination for their degrees."

We believe that the Aberdeen graduates are about to adopt a similar course, and it was intimated by several at the meeting that in this case the St. Andrews Association would cordially co-operate in any measure for the common good. We may add that the Association intends to compile a list of St. Andrews graduates, showing what appointments they hold, or have held, and what other qualifications they possess. We should therefore urge upon all at once to join the Association, and while remitting the small subscription to the Secretary to furnish him with these particulars corrected to date.

## THE INSTITUTION OF CIVIL ENGINEERS,

MAY 21, 1867.

JOHN FOWLER, Esq., President, in the chair.

The paper read, in abstract, was "Experiments on the Removal of Organic and Inorganic Substances in Water," by Edward Byrne, M. Inst. C.E.

It was premised that the object of these experiments was to try how far the statements generally made, with regard to the action of charcoal in purifying water, might be depended on. They were not undertaken to support any theory, but rather to satisfy the Author himself, who observed every precaution to obtain trustworthy results.

It was stated that many substances were spoken of as having a purifying effect on water, but of all, charcoal (especially animal charcoal) had been considered the most efficacious. Though in works which treated on spring and river waters, the assertion was constantly made, that both vegetable and animal charcoal (particularly the latter) removed the organic and inorganic substances found in waters, yet no experiments were given by which to judge to what extent these statements were true. With a view to ascertain whether water, uncontaminated by either decomposing animal or sewage matter, but containing dissolved vegetable matter, would contain any nitrogenous bodies, some bog water was procured from a locality that precluded the possibility of its containing any animal or sewage matter, the experiments on which served to prove that, in bog water at least, vegetable nitrogenous matter was present.

After some observations to the effect that nitrogenous organic matter might exist in water in an innocuous state, and that as putrefactive nitrogenous matter was the most hurtful of all substances that could exist in water, the Author remarked how much it was to be regretted that, by chemical means, no distinction could be made between the nitrogenous organic matter which existed in a putrefactive, and that which existed in a non-putrefactive state.

The details of four sets of experiments were given, the first on animal charcoal, of which nearly 5 lbs., new, and freshly burned, and of the degree of fineness used in sugar refineries, were packed in an ordinary stoneware filter. The water employed (of which a complete analysis was given) contained, in the gallon, organic matter, 10.80 grains; inorganic matters 83.30 grains. The hardness of the water, before boiling, was found to be 50°50', and after boiling, 33°; and the oxygen required to oxidize the organic matter contained in one gallon, amounted to 0.0116 grain. Several gallons of the water were

allowed to percolate slowly through this charcoal, and upon examination, afterwards, it was found that, of the inorganic matter which had originally existed, 52·60 grains were removed from the first gallon; but from each succeeding gallon less and less; so that, from the twelfth gallon of water that passed through the charcoal only 8·80 grains of inorganic matter were removed. Of the organic matter 4·80 grains were removed from the first gallon; but, with a gradual decrease, the charcoal ceased to remove any organic matter after the sixth gallon. In fact, immediately afterwards, it commenced to give back a portion of the organic matter removed in the first instance, the quantity returned to the twelfth gallon amounting to 1·55 grain. Thus, of the 13·54 grains of organic matter removed by the charcoal from the first six gallons of water, as much as 4·98 grains were given back to the next six gallons; from which the Author concluded that, had this set of experiments been carried a little farther, all the organic matter removed at first by the charcoal would have been given back again.

The second and third series of experiments were with wood and peat charcoal, which, however, were still less satisfactory than those with animal charcoal. The fourth set of experiments was on animal charcoal, with water previously treated with permanganate of potash slightly in excess. After remarking that the water, in its passage through the charcoal was found to contain organic matter, apparently in the same quantity as before treating it with the permanganate, attention was drawn to a comparison between the first and fourth sets of experiments, to show how closely they agreed to contradict the general statements made as to the removing power of charcoal, and to demonstrate how very little indeed could be done by this filtering material, even on a small scale, towards the purification of water.

The author then said that as the epidemic which had so recently left these shores might return again before the adoption of any scheme to supply the Metropolis with an abundance of pure water, he thought it would be well, if only to check its ravages in ever so slight a degree, to experiment on various materials which were believed to possess the power of removing organic matter; but, to obviate false conclusions, and to render such experiments practically useful, they must be systematic.

In conclusion, he gave it as his opinion that, as by chemical agency bad water could be purified to a very limited extent only, the public mind should more than ever be given to the great question of supply; and, as people valued their lives, they should above all things, in their choice of a source, not be too much influenced by distance, but be willing to undergo the necessary expense of securing the object of their search, not only in abundance, but in the greatest purity.

## Hospital Reports.

### ST. BARTHOLOMEW'S HOSPITAL.

ACUTE SUPPURATION IN THE KNEE-JOINT AFTER A PUNCTURED WOUND: FREE INCISION: RECOVERY.

Under the care of Mr. COOTE.

MARCH 20, 1867.—Jane T., æt. 14, a slightly-made girl, was sweeping a cocoa-nut matting on her knees, when a pin was pressed out, which ran into the right knee, and caused her to start with pain. She pulled the pin from the limb, where it had penetrated the greater part of its length over the situation of the synovial membrane. The day following she had a great deal of kneeling work, when she first found the joint somewhat stiff and painful. She applied a poultice on the same night, but continued her work the day following, the pain becoming more severe, until she was unable to continue her occupation, and finally came to the hospital, where she was admitted April 1.

The whole limb was greatly swollen, and there was extensive suppuration round the knee-joint. The synovial cavity was full of fluid, which Mr. Coote pronounced in all probability to be pus. Free incisions were made to let out the matter formed external to the synovial cavity. A large poultice was applied to the limb. She was ordered mutton-broth; four ounces of wine daily; arrowroot; and

a draught composed of ammonia, chloric æther, and tinct. of ipecuona, three times a day.

April 2.—The relief afforded by the incisions is only partial; the countenance is expressive of much suffering; she has no appetite, nor can she rest at night. Opium was administered at night, and the wine was increased in quantity, but the symptoms generally became more severe; and on the 14th it was found that the swelling was of firmer consistence, and was rapidly extending up the thigh. Mr. Coote made a free incision into the synovial cavity, the whole length of the joint, when there escaped nearly twelve ounces of thick, well-formed matter. The operation was performed while the girl was under the influence of chloroform, so that she suffered no pain.

From that time to the present, the pain and swelling have gradually subsided, and she is now convalescent, the wound having, in great part, closed by granulation and cicatrism. The limb is in very good position, and she has gained flesh, and is in usual spirits.

May 30.—Convalescent.

This case illustrates the serious consequences which may ensue from a penetrating wound of joint. As has been observed by the late Mr. Hay, patients rarely recover without the suffering caused by this formation of pus. It was estimated by the size of the wound that full forty ounces of pus were evacuated by the various incisions in this case.

The relief afforded by the incision into the joint was here almost immediate, but the danger of such a proceeding was strongly pointed out by Mr. Coote. It is only in cases where the tension is very great, and the danger of the extension of the suppuration upwards is immediate, that the operation is justifiable, and then the incision must be free, so as to offer a free outlet to the contained matter.

## MATER MISERICORDIÆ HOSPITAL.

### CLINICAL REPORTS BY DR. HAYDEN.

ACUTE RHEUMATISM WITH PERICARDITIS; ALKALINE TREATMENT; RECOVERY.

PATRICK M., aged 31, a corn porter, was admitted into hospital November 12, 1866. A fortnight previously he was hard worked in loading corn; perspired copiously, and, during the intervals of rest, neglected to put on his coat, and became chilled. On the following day he had a slight rigor, and pains in the shoulders, but continued to work till Wednesday, November 7, when he was obliged to keep his bed, and on the 8th he had pains in the wrists and ankles. On admission the tongue was loaded; pulse 102, full and regular; pain in wrists and ankles, the latter being slightly swollen; he perspired freely, and had a severe cough with mucous expectoration. Ordered a mixture containing wine of the seeds of colchicum, tincture of opium, nit. spirit of ether, and liquor potass; also an expectorant mixture.

From the date of admission (12th), till the 20th, no noteworthy change took place; the pulse varying from 102 to 120; the urine being acid, and loaded with lithates.

On the 20th a well-pronounced friction-sound was heard over the base of the heart; pulse 102; respiration 22. Three leeches were applied over mid-sternum, and subsequently a warm poultice; and a mixture was given consisting of liquor ant. tart., ℥ii.; tinct. opii, ℥i.; acetat potassæ, ℥ii.; Syrupi Croci, ℥ii.; aquæ camphoræ ad ℥viii.; an ounce to be given every third hour.

On the 22nd, the pulse was 114, full, but soft and vacillating; a slight frotement was heard over left base of heart at the end of expiration; loud bronchitic râles audible all over front of chest.

A large blister was applied over the heart, and the following mixture was given—viz.:—Potassæ nitrat., ℥ii.; ammon. sesque carb., ℥i.; liquor potassæ, spirit ether nit. aa. ℥ii.; aquæ camphoratæ ad ℥viii.; st. ℥ss. 2nd quaque hora.

On the following day (23rd) the urine was slightly alkaline, and on the 24th the pulse had fallen to 102, and was full and regular; tongue cleaning; slight friction still audible over left base; urine highly alkaline, and effervesced briskly on the addition of nitric acid; specific gravity 1025, free from albumen.

25th.—Patient quite free from pain; pulse 102, strong and regular; tongue perfectly clean.

26th.—Pulse 108; two distinct "rubs" are audible over the base of the heart at the acme of inspiration.

27th.—Friction audible over base of heart; it precedes the first sound, and is loudest during inspiration. No further change occurred till the 30th, when a distinct frotement was heard during inspiration only, preceding the first sound, and propagated a short distance in the course of the aorta. The patient was allowed to be out of bed to-day, and has been taking, up to this date, the alkaline mixture prescribed on the 22nd: this was stopped, and quinine was given in gr. ii. doses, three times daily.

On the 4th December a friction murmur was heard during the second sound over the left margin of the sternum, at the level of the third intercostal space, but not propagated farther in the course of the pulmonary artery.

On the 8th no friction sound was audible; on the 10th the patient had greatly improved in strength and appearance; and on the 15th he left hospital quite restored to health.

In this case the signs of pericarditis were not developed till seven days after the date of the man's first illness, and, during the period of its continuance, the friction sound varied in a remarkable degree both in site and in rhythm.

It was usually audible only at the acme of inspiration—a circumstance which I regard as evidence of its pericardial origin, and auricular site, and am disposed to attribute to the state of distension of the auricles consequent upon the influx of blood from the venæ cavae during inspiration.

In regard to the action of the heart, the murmur immediately preceded the first sound, and might, therefore, be possibly confounded with the præ-systolic murmur of mitral constriction; but from this it was distinguishable by its basic site, and by its being audible *only* during inspiration.

The beneficial action of alkalis, given till the urine became alkaline, is forcibly illustrated in this case. The alkaline diuretic mixture was prescribed on the 22nd, the urine being then highly acid; pulse 114, vacillating. On the following day the reaction of the urine was slightly alkaline; and on the 24th, when it was reported as highly alkaline, and effervescing on the addition of nitric acid, the pulse had fallen to 102, and was full and steady; the tongue cleaning from the edges; and on the 26th the patient was quite free from pain.

#### ACUTE RHEUMATISM WITH IRREGULAR AND INTERMITTING ACTION OF THE HEART; TREATMENT BY ALKALIES; RECOVERY.

Patrick R., aged 22, draper's assistant, admitted 23d of November, 1866. Previous health good. For the last few months had been constantly exposed to a draught in the shop in which he did business, and about ten days previously caught a severe cold, followed by cough. On admission his tongue was coated and white; pulse 106, regular, and full. He complained of great pain in the joints of the right side of the body, the ankle and knee being much swollen. The left wrist and ankle were likewise painful, but not swollen. No abnormal cardiac sign, with exception of an occasional reduplication of the second sound. The urine was acid. The alkaline mixture given in the preceding case was prescribed, as likewise an expectorant mixture.

On the 25th there was a remarkable rhythmical irregularity of the heart and pulse, *i.e.*, the action became accelerated after every fifth beat. The patient was constantly sighing, and appeared slightly incoherent. Urine still acid; 1030 s. g., and free from albumen. Skin dry. To have  $\zeta$ iv. of wine daily.

26th. Urine neutral, and high coloured; pulse 96, feeble, and irregular. Patient very uneasy, and complaining of severe pain in the joints. At six P.M. the alkaline mixture was discontinued, in consequence of the occurrence of diarrhoea, which was promptly arrested by the use of the acid astringent mixture (dilute sulphuric acid and tincture of opium). Alkaline mixture resumed.

27th. Patient feels and appears much better; pulse 90, and regular; heart's action also regular, and more vigorous than previously; there is copious perspiration, and the urine is neutral.

28th. Patient was delirious last night; pulse 84, regular; urine alkaline; perspiration arrested. To have mixture only every fourth hour. From the above date till Dec. 3, the pulse ranged from 96 to 102, and on that day the tongue had become clean, and the pulse was 96 and strong. Lemon juice was now substituted for the alkalis.

On the 10th the patient was allowed to sit up, and on the 13th gr. ii. of quinine with m. x. of liquor of the pernitrate of iron were given instead of the lemon juice, three times daily.

20th. Patient now takes walking exercise in the corridor. Urine faintly alkaline; pulse 102 in erect, and 84 in sitting posture, but irregular in both. The action of the heart is now peculiar, as exhibiting rhythmical irregularity, intermittence, and suppression of the first sound. Thus, there are four beats in quick succession, and at equal intervals, during which no first sound is heard; these are succeeded by a long interval, a single beat, and an equally long interval, in the order in which they are mentioned; and during this single beat the first sound is distinctly heard. The above-mentioned series of phenomena is then repeated without any variation, except that occasionally there are only three in place of four rapidly consecutive beats.

22nd. The pulse was 90, regular, and of moderately good volume. No first sound was audible at the apex, but at the base a first sound was faintly heard. Urine acid; specific gravity, 1030; free from albumen.

24th. Pulse 96 and occasionally intermitting; first sound of heart distinctly audible at apex; tongue clean; appetite good. Discharged.

The preceding case exhibits a state of the heart in rheumatism similar to that occasionally witnessed in typhus fever, in regard to the suppression of the first sound. This phenomenon is of rare occurrence in rheumatism, and is probably due to the action on the heart of the morbid poison (lactic acid?) of that disease. The remarkable irregularity of the heart's action, which I would designate as *rhythmical*, because occurring at regular and equal intervals, constitutes another interesting feature in this case. This form of irregularity I believe to be peculiar to *neuroses* of the heart, as distinguished from organic disease.

The favourable change in the general condition of the patient, and in the individual symptoms, coincident with the change in the reaction of the urine under the use of alkalis, is likewise of practical interest.

## Reviews.

BODY AND MIND: the Nervous System and its Derangements. By GEORGE YEATES HUNTER. London: John Churchill and Sons.

OUR first impressions, from the outside appearance of this little book, was not favourable. We feared from its external resemblance to some of the domestic medicine books, that it was of the same order. We have, however, conscientiously read every line, and most readily assure our readers that it contains nothing objectionable. Its title, indeed, is vague and inexact. There is very little about the mind in it, but there is plenty of good advice about the care of the body, and that in a very readable form. The book is of course addressed to the public, and as such will not be expected to contain anything new to the profession. It may be fairly divided into two parts; the first devoted to the preservation of health, and the

second to a consideration of certain derangements, which the author considers most productive of nervous diseases.

It is the first portion of the book that we think the more successful, consisting as it does of a series of plain and practical observations and directions on education, diet, exercise, clothing, bathing, sleep, residence, ventilation, change of air, and some often forgotten avoidable causes of nervous ailments, such as the cares of business, speculations, mental labour, and anxiety, the abuse of alcohol and tobacco, as well as certain mental stimulants, such as sensational reading and religious excitement. The observations on each of these subjects are pithy and pointed; and the book, had it been confined to this subject, which is complete in itself, might even have been extended with advantage. The second portion is perhaps as fairly done as could be expected. It makes no attempt to enable every one to be his own doctor, but is confined strictly to such particulars as a patient may, without prejudice, consider. It may indeed be questioned whether there is any advantage in an invalid looking over a description of disorders of the several viscera; and we do not altogether like such subjects as hysteria and uterine derangements to be read about by females. They are better entirely let alone, and, in our opinion, if these chapters were excised, the book might, with advantage, be placed in the hands of almost any one. We cannot, therefore, do other than congratulate the author on having produced a neat work of moderate compass for popular use, free from every vestige of quackery.

It is so difficult to write for the public on professional topics that, with so much in its favour, it would be ungenerous to point to the defects of the work. The author modestly excuses his style. There was no need for apology. We have no sympathy with that class of critics which would reduce every book by a professional man to the most unreadable form. The best style is as suitable for scientific writers as for those who confine themselves to literature proper. A judicious use of the pruning-knife will enable the author of the book before us to write with a certainty of being read, and this is perhaps as much as he could expect to have achieved in his first attempt.

**LIGHT: its Influence on Life and Health.** By FORBES WINSLOW, M.D., D.C.L. London: Longmans.

OUR first impressions on taking up this handsome little volume were of a very conflicting character. In the first place it is so elegant in its appearance, its type so clear, and its size so handy, that it seemed to promise that reading its 300 pages would be a most agreeable after-dinner occupation of an hour or two, and the name of the author was sufficient guarantee that the perusal would be pleasant enough. Had the publisher saved us the trouble of cutting the leaves, it would have been an extra advantage, since the volume only needs the attractions of bevelled or gilt edges to make it suggestive of the drawing-room table. It always seems odd to us that, when publishers bestow so much expense on bringing out a work, they should not invariably prevent the slight disfigurement which results from cutting open.

On the other hand, the reflection would intrude upon us that, with this small 8vo page, and double-leaded type, there could scarcely be so much of Dr. Winslow's thoughts in the book, as we should like to have the pleasure of reading.

We have read the book through, and may candidly confess we have not got rid of our conflicting ideas about it. We find the perusal, as we expected, pleasant recreation. Dr. Forbes Winslow is necessarily readable, and has here thrown together, with the art of a practised writer, a large amount of learning and numerous facts bearing upon his subject. Yet, as if to verify our presentiment, we find less of his own thoughts than might have been expected. He gives so fully other men's views, and quotes them so liberally, that he seems to have no space left for his own conclusions, and, in some instances, we really feel, after all, that he has, while writing on *light*, left us in the *dark* as to his own opinions. Having ventured on this statement, we may be expected to confirm it by an example. We will therefore select one, not because it is the most prominent, but because it relates to a point on which we should naturally have anticipated something decisive from the nature of the author's extensive experience. The third chapter is on "the alleged influence of the moon on the insane," and occupies thirty-five pages. Yet, the only expression of the author's own views on this most interesting subject is contained in a paragraph of nine lines, and which we will therefore quote:—

"If I were to confine the concluding remarks to the result

of my own observations on this subject, I fear I should be able to add but little to what others have written in relation to it. I freely admit that, placing but little faith in what has been recorded or said on the subject, I have not kept any systematic register as to the effect of different phases of the moon on the insane."

We freely admit that the reason assigned for having little to say is a good one, but we trust the author will appreciate our disappointment when we thus readily express ourselves as preferring his own ideas to the most excellent *resumé* of those of others. Men of inferior mould, and less opportunity, may be safely left to anything approaching the work of compiling, and we should therefore be better pleased to receive from Dr. Winslow his own thoughts, than the most careful and discriminating epitome of the literature of his subject. Although the form of words we have employed may almost seem a complaint, they are, nevertheless, those of praise, since we are, in effect, asserting that what we might commend as valuable in another, does not, in our opinion, come up to the full standard of Dr. Forbes Winslow himself.

His previous works have set up the standard, and we feel sure he will be rather pleased than otherwise that we should measure this by it.

In another aspect, however, the book is deserving of success. It is written for the general public, and, as such, is one of the best books that can be widely circulated. A full and able summary of the sanatory and physiological influence of light; written in a fluent style; containing the opinions of ancient as well as modern philosophers, classified with learning and acumen; it constitutes a really valuable contribution to the literature of the day, and should be read by every one who is willing to devote an evening to so intellectual a recreation.

That the scientific teaching is fully brought down to the latest standard would, of course, be expected; and this, on careful perusal, we have found to be the case. Dr. Winslow has pressed into his service the most recent investigations, by means of the spectrum, and shows that he is quite *au courant* with the last speculations respecting the metallic vapours found in the atmosphere of the sun, and their possible connection with the hygienic influence of sun-light.

What a difference there would be in this class of literature if other authors were equally well-informed. We trust a few of those who aspire to impart scientific knowledge to the public will take the hint. Let them take Dr. Winslow's book as their guide, and they will not confine their attention to doctrines that have been exploded a dozen years.

One of the greatest faults of our popular scientific books is that they are behind the age. Dr. Winslow has set an example which we hope will be followed. He has brought it down to the present date.

## CURRENT LITERATURE.

*Practical Dissections*, by RICHARD M. HODGES, M.D. Second Edition. Philadelphia: Henry C. Lea. London: Trubner and Co.—This is a small volume which will serve well as a dissecting-room companion. That it was accurately done at first is attested by the few changes required in the second edition. Of course it is not a book to read except as a guide, and the writer of this notice has not read it through. He has, however, compared the plan of the volume with other books on anatomy, and has carefully read the general hints on dissection, which are admirable, and also the whole of the chapter devoted to such anatomy as can be demonstrated without actual dissection. This is founded on an article by Mr. Luther Holden, in St. Bartholomew's Hospital Reports, and we think that eminent anatomist and surgeon will be gratified to find his suggestions thus admirably carried out. Dr. Hodges' book will be a great acquisition to the student. It is brought out in a most portable form; it is, in fact, reduced to the essentials for the dissecting-room, and, as a book to work with, is very properly strongly bound. No plates are introduced, as the student is supposed to have the subject before him. Whatever other manuals of anatomy he may have, we should advise the addition of this inexpensive one to his library. It can be carried in the pocket without inconvenience, and will serve to save his others. Had we our own time to go on, we should certainly make trial of Dr. Hodges' *Practical Dissections*.

*Shaw's Medical Remembrancer.*—This favourite pocket-book for emergencies, has reached a fifth edition. It is now edited, and, to a great extent, re-written by Mr. Hutchinson, of the London Hospital—a sufficient guarantee for its accuracy. Among the new matter introduced into this edition, we may mention the articles on injuries to the head and spine. The alphabetical arrangement certainly is most convenient for reference.

In the form of an *Appendix* to its 18th Annual Report the *Prudential Life Office* has issued a volume of tables of vital statistics, which will probably interest those of our Profession who occupy themselves with this subject. If all companies would publish their experience on a uniform plan, we have no doubt that a valuable amount of reliable information would be rapidly accumulated. The tables issued by the PRUDENTIAL are illustrated with coloured diagrams, showing the varying mortality in different districts and periods.

### THE PROCEEDINGS OF THE GENERAL MEDICAL COUNCIL.

#### A RETROSPECT.

If the space to which our medical contemporaries allocate to the proceedings of our much abused Medical Parliament, be an index of the interest with which they are regarded by the Profession, it is manifest that the topics therein discussed, are voted by an immense medical majority of the public, to be worthy of most earnest attention, and that if the Medical Council be inefficient for the reform of the Profession, it is not because there is not plenty of work for them to do, and great incentives to action. If we have had a difficulty in providing our readers with a *resume* of the proceedings, it has been in the effort to stem the tide of irrelevancy and of personal squabbling, which mars the usefulness of the Council and the dignity of its Members, and to extricate the fly from the pot of oratorical ointment.

The Session opened on Wednesday the 29th of May, and the meeting once more took place in the spacious and convenient room, placed at the service of the Council by the College of Physicians. Whilst such premises are available, it is to be hoped the Council will make no attempt to procure a building of their own, which could not possibly add to their

convenience or comfort, but would undoubtedly entail a large and unremunerative outlay.

The opening address of the President, Dr. BURRELLS, was listened to with profound attention, and furnished a clear statement of the doings of the Council, and its claims to respect. Spoken clearly and incisively, with no attempt at display, it exactly hit the mark, and furnished an admirable introduction to the business of the day. Hardly had the President resumed his seat when the combativeness of the Council was aroused into full energy by a communication from the Home Secretary, respecting the Medical Amendments Act. It will be remembered that last year the draft Bill was forwarded to Sir GEORGE GREY, then Home Secretary, who, in going out of office, transferred it to the care of Mr. WALPOLE. In July last, the Executive Committee of the Council waited on that gentleman, “to press on the Government the expediency of its being adopted as a Government measure, and at the same time to state that the Medical Council are of opinion that unless the Bill be introduced by the Government, it would be inadvisable to proceed with it.”

It is almost unnecessary for us to say that the usual diplomatic put-off was dealt out to the Council with the usual implied promise, that something would be done. After six months, the Council were informed, through their President, that the Home Secretary was busy, and they had better take their Bill elsewhere. This suggestion being contrary to the express determination of the Council, could not be adopted; and in May, Mr. WALPOLE was again dunned into a promise of settling the little account shortly. The settlement was now presented to the Council, and it may be paraphrased in tone and substance as follows:—“The delay is all your own fault, because you were naughty, and would not vote what you were bid. If you are good boys and will swallow what your Papa desires, he will not whip you and put you in the corner. In any case you must not tease him any longer, but get ‘some independent member’ to mend your toy, and if you can get any one, Papa will give him leave to do so. But you must not be selfish, and must let in and play with any quack whom your dear Papa, or any of his friends, may desire.”

In other words, after nine months of culpable disregard and carelessness for the public interest, Mr. WALPOLE promises that if the Council will consent to accept “any Colonial or Foreign Degree, Licence, or Diploma” which “any of her Majesty’s Secretaries of State” may think worthy, he (Mr. WALPOLE) “does not think the Government would offer any opposition to the Bill,” but it would be well for the Council to entrust the Bill to some independent member.

Just indignation was naturally expressed at the

MEETING OF THE  
GENERAL MEDICAL COUNCIL  
OF EDUCATION AND REGISTRATION.

(Continued from page 567.)

Dr. ALEXANDER WOOD thought the holders of Colonial degrees would use an expression which was very common in Scotland: "Thank you for nothing." "We asked of you bread, you give us a stone." He thought there was very little liberality in this—the liberality that had been so much boasted of. The motion of Dr. Paget was a well considered scheme to meet the difficulties that had arisen, which, if it were carried, would place the Council in exactly the same position it stood prior to the passing of the last Medical Act. It enabled them to do for men with foreign and colonial degrees received subsequent to the year 1858, what it did for those before the passing of the Act in that year. He begged to support the motion, as he considered it an admirable solution of a very difficult question.

Mr. SYME was of the same opinion.

Dr. RISDON BENNETT thought it extremely desirable there should be a distinction, as suggested by Sir D. Corrigan. If those possessing colonial and foreign diplomas were to be admitted to the same position as our own—and the Government insisted that it should be done—the question was, how were they to do it, and what was the best plan of going about it. The Government had said, you *must* have a door for the admission of these men. He thought, therefore, that they should show the Government the reasonableness of their submitting to a certain examination prior to admission. Although he could not see the utility of the amendment of Sir D. Corrigan, he hoped Dr. Paget would be induced to slightly modify his proposition that the distinction between the two diplomas might be more marked. He should have great pleasure in voting for its adoption.

Dr. FLEMING quite agreed with the remarks that had fallen from Sir Dominic Corrigan. He thought it was absolutely necessary there should be a distinction between foreign and colonial diplomas, those from America especially were heaped upon them indiscriminately. He had been recently on the Continent, and had watched the nature of the examinations there, and he had no hesitation in saying that, compared with those enforced upon our own students at home, they were quite inadequate, and certainly did not fit them to be placed side by side with those who had acquitted themselves before the Examining Boards of this country, he would therefore second the amendment.

The PRESIDENT suggested that before proceeding with the motion under discussion the Council should know exactly in what position they were placed with the government. At the interview he had sometime since with Sir George Gray, the right hon. gentleman intimated that the government would not consent to pass the "Medical Act," unless some clause were inserted, for the admission of foreign and colonial diplomas. He did not know what the answer of the present government would be on the point, but he had reason to believe that Lord Derby would not consent to a distinction being made.

Dr. ANDREW WOOD said the Council must recollect that they were pledged to the government that a clause should be introduced for the admission of these diplomas; aye, and pledged to the introduction, even though it were without any examination whatever. This being the case, he thought the present clause a great improvement upon that of last year, and he hoped the Council would adopt it. Mr. Walpole's proposition was quite inadmissible. He hoped the present Home Secretary, Mr. Hardy, would see this; if he did not, then he would suggest that the Council throw the onus of passing any measure on the Government, and refuse to have anything more to do with the matter.

Dr. PAGET said that as the objections taken by some members to the motion brought forward by him had been answered by subsequent speakers, he need not trouble the Council with a reply. He thought a clause for the separation of colonial and foreign diplomas was provided in the motion now before them.

The amendment of Sir Dominic, seconded by Dr. Fleming, was then put from the Chair, and negatived, and the motion of Dr. Paget agreed to by a large majority.

The following motion by Dr. ACLAND was withdrawn by consent of the Council, to a future occasion:—

"SUGGESTIONS FOR ENABLING CLAUSES IN A NEW  
MEDICAL ACT.

"1st. That it is desirable to obtain the following additional powers under the Medical Act, with respect to examinations, viz.:

"Whereas there are now in the United Kingdom, nineteen Licensing Bodies, having power to confer thirty separate Licences and fifty-three different Titles, and whereas it was the intention of the Medical Act to produce a uniform and sufficient standard in the Examinations conducted by the said Licensing Bodies, and whereas the power of combining the examinations of the said Licensing Bodies under Clause XIX. of the Medical Act has been sparingly used; whereas the visitation of the Examinations of so many Bodies by different Visitors is a cumbrous form of procedure, and one ill calculated to produce the uniformity sought for, and that further concentration of the Examinations will tend to the accomplishment of that object.

"2nd. That in order to encourage the study of Hygiene and 'State Medicine,' it is desirable that the Council shall, in combination with any of the Licensing Bodies, have power to institute Examinations in Hygiene and 'State Medicine,' and to give Certificates of competency therein, and that these certificates may be entered upon the General Register, as an additional Qualification or Title of registered persons.

"3rd. That whereas it is the duty of the Medical Council to republish, *alter, and amend the British Pharmacopœia*, lately published (Clause 54, Medical Act), and the Council have resolved that they do not consider that they have power under the Medical Act to expend any funds in enquiring into the utility of articles introduced into the *Pharmacopœia*, but only how to prepare such articles; *it is desirable* that the Council shall have power to expend such sums as it may see fit from time to time, with the approval of the Treasury, on investigations calculated to perfect the knowledge and to test the utility of articles of reputed or probable value, whether recently discovered or otherwise, with a view to including them in, or rejecting them from, future editions of the *British Pharmacopœia*.

The following report from the Committee on Mr. Richard Organ's application was read and passed:—

"The Committee, having examined the documents accompanying the application of Mr. Richard Organ, and having taken into consideration the circumstances of Mr. Organ's original offence, his subsequent course of defence, and the careful decision of the Council on a similar petition, arrived at last year after full deliberation,—Recommend that the Council decline to entertain Mr. Organ's application.

"(Signed) ALLEN THOMPSON, *Chairman.*"

The Executive Committee for the ensuing year, was then constituted on vote by ballot as follows:—

The President; Dr. Paget, 22; Mr. Cæsar Hawkins, 21; Dr. A. Smith, 21; Dr. Sharpey, 21; Dr. Andrew Wood, 20; Dr. Acland, 13.

THURSDAY, JUNE 6.

After the minutes of the preceding day had been read and confirmed, the PRESIDENT said before proceeding with the business of the day, he had to inform them that the deputation appointed on the previous day to wait upon Her Majesty's Government relative to the proposed clause

in the New Medical Act, had had that morning an interview with the Right Hon. Gathorne Hardy, by whom they had been very courteously received, and the remarks which he (the President) made, supplemented by those which fell from some members of the deputation, had been listened to with marked attention. Mr. Hardy entered into the subject very fully, stating that he well remembered the circumstances connected with the passing of the Medical Act in 1858, and although in the present stage of government business he did not feel himself in a position to promise the immediate introduction of the bill before parliament, he, nevertheless, would take the earliest opportunity of conferring with the late Home Secretary, Mr. Walpole, who was perfectly conversant with the subject, and he would then put himself in communication with the council.

Professor CHRISTISON said that as the matter, at least so far as the council were concerned, was at an end, to prevent the time of the council for the future being unnecessarily taken up he would propose

“That it be delegated to the Executive Committee to resume its conferences with the government, with regard to the bill for the amendment of the Medical Act as now adjusted by the council, and to take such steps as they may think advisable towards carrying the bill through the legislature in the same manner as the Medical Act itself.” This proposal was seconded, and carried *nem. con.*

It was proposed by Sir DOMINIC CORRIGAN, seconded by Dr. STOKES, and passed:—

“That the returns from the Directors General of the Army and Navy Medical Departments be placed on the minutes, and that the thanks of the council be given for them.”

THE FOLLOWING TABLE, COMPILED FROM THE RETURNS FOR THE EXAMINATIONS IN MARCH AND AUGUST, 1866, AND FEBRUARY, 1867, GIVES THE GROSS RESULT:—

Name of Licensing Body.	No. of Qualifications.			Deficient in.				Percentage of Failures to Qualification.

LETTER FROM THE DIRECTORS GENERAL OF THE NAVAL MEDICAL DEPARTMENT.

“Admiralty, W.C. 30th March, 1867.

“SIR,—We have the honour to acquaint you, for the information of the General Council of Medical Education and Registration, that during the year 1866 nineteen candidates presented themselves for examination for Medical Commissions in Her Majesty's Naval Service.

“1st. Of these, eleven passed more or less satisfactory examinations, and were admitted into the service, and eight were rejected.

“2nd. Three of the eleven who were admitted into the service passed good examinations in all subjects; one who otherwise passed a good examination was somewhat deficient in Latin and Botany; four passed moderately good

examinations; and in three the examination passed was indifferent.

“3rd. One Candidate, who passed a good examination in all subjects, had been once previously examined and rejected, and the same observation applies to one who passed a moderately good examination. The candidate who passed a good examination with the exception of Latin and Botany had been twice previously examined and rejected.”

“4th. Of those who were rejected three failed in their Classical Examination. One of these, however, was found to be also physically unfit for the service, and one of the others was so ignorant of the Latin language that he declined to attempt to translate, and failed to write an ordinary prescription.

“5th. The remaining five were rejected for ignorance of anatomy and surgery chiefly.

“6th. Appended hereto are lists of the subjects upon which the candidates were orally examined, the questions forming the subjects for their written examination, and a tabular statement, showing the qualifications of the different candidates according to Schedule (A) of the Medical Act, the results of the examinations in each case, and the subjects in which the candidates were most deficient.—We have the honour to be, Sir, your obedient servants,

J. W. SALMON, M.D., *Deputy Inspector-General.*  
WM. R. E. SMART, M.D., *Deputy Inspector-General.*  
ALEX. E. MACKAY, M.D., *Deputy Inspector-General.*

The following is the text of Dr. Alexander Wood's report on the subject of preliminary education, which opens with this preamble:—

“Your Committee are satisfied that the importance of the subject of General Education, fully warrants the attention which it has received at the hands of the Council from the commencement of its labours until the present time.

“It is obvious that proficiency in medical study must be to a great extent affected by the ability conferred on the medical student by previous mental training, to profit by the lessons of his medical teachers, and that a sufficient general education in literature and science, obtained before the commencement of professional study, will go far to secure the entrance into the profession of men who will do credit to it by possessing such a degree of enlightenment of mind, derived from literary acquirement, as will secure the respect of the educated persons with whom they may be afterwards brought into relation in the course of their professional duties.

“In 1859 the Council agreed to a series of recommendations, which were repeated from year to year with various additions, until in 1866 they were sent out to the various licensing bodies in the subjoined form.

“Your Committee are of opinion that it would be unwise to disturb, this year, recommendations carefully considered by the Council last Session, which have not yet had a sufficient trial, and some of which have not yet come into operation, especially as the visitors of examinations give in most cases a satisfactory report of the manner in which the examinations in general education are conducted, the Committee are, however, of opinion that the time has come when the Council, without going beyond the minimum adopted in 1866, should indicate more precisely how the knowledge possessed by students of the subjects contained in that minimum may be best tested. Further, your Committee are of opinion that the Council should consider how far it might be possible for them, by friendly communication with the national educational bodies, to whom they have repeatedly recommended that general education should be entrusted, to secure some means of visiting their examinations, and of making suggestions in regard to the mode of conducting them of a similar nature to those which have proved beneficial in regard to professional examinations.

“It is very evident, as indeed the reports of the visitors of examinations demonstrate, that the subjects contained

in the minimum laid down by the Council may be variously understood, and the Examinations may be variously conducted by the examining bodies.

"1. For example: 'English language, including grammar and composition,' as recommended in 1866, may be a sufficient test in the hands of one examiner, and insufficient in the hands of another; in fact, the test may be so applied as utterly to fail in preventing the entrance of illiterate persons into the profession.

"Your Committee would recommend that in re-issuing this recommendation notes to the following effect should be appended:—

"The General Medical Council will not consider any examination in English sufficient, that does not fully test the ability of the candidate—

"1st. To write a few sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition. 2nd. To write a portion of an English author to dictation. 3rd. To explain the grammatical construction of one or two sentences. 4th. To point out the grammatical errors in a sentence ungrammatically composed, and to explain their nature. 5th. To give the derivation and definition of a few English words in common use.

"2. ARITHMETIC AND ALGEBRA seem not to need any comment.

"3. GEOMETRY—*First two books of Euclid.*—It is obvious that an examination conducted under this brief instruction is not necessarily efficient, unless the questions be so put as to exclude the deception which may arise from the Candidate answering without real knowledge, merely through the help of a powerful memory and careful 'cramming.' Precautions therefore should be taken against this risk, and to secure that he possesses a real knowledge of the subject.

"4. LATIN.—It is 'perhaps' in Latin, next to English, that the Committee think it necessary that the Council should recommend what would, in their opinion, constitute a satisfactory examination. Your Committee would suggest—

"1st. That the candidate, with the aid of a dictionary if required, should be required to translate three or four sentences from an easy author, not having been informed beforehand from what author the sentences will be selected. 2nd. That he should be required to translate easy sentences from English into Latin, either with the aid of a dictionary or on being furnished with the Latin words, altered in order, number, case, mood, and tense. 3rd. That he should be required to parse a Latin sentence, so as to show his acquaintance with the Latin grammar.

"Your Committee would consider it more satisfactory if the preliminary examination were made in every case to include an oral as well as a written examination. They are well aware that there are great difficulties in the way of such an arrangement, but still they would recommend the Council to encourage it as far as it may be practicable.

"Your Committee are of opinion that the minimum of general education laid down in 1866 will eventually require alteration, but as the Report of the Royal Commission in Scotland very recently published on the school education of that country, and the Report of the English Royal Commission, now in course of preparation, will throw much light on the school education of both countries, the Council will hereafter be enabled to judge more accurately both of the amount and of the kind of knowledge that can be fairly demanded of well-educated youths of 16 or 17 years of age.

"The last subject on which your Committee would touch, is the question by what Boards the Examinations should be conducted. They still adhere to the opinion, early expressed in this Council and never deviated from in former reports on the subject—"That, as far as may be practicable, testimonials of proficiency, granted by the National Educational Bodies, be accepted as sufficient evidence of a student's acquirements in general education,

and that the examination on general education be eventually left entirely to the Examining Boards of National Educational Bodies recognized by the Medical Council."

"Your Committee fear that a too liberal interpretation of this resolution has led to the admission of several bodies on the list whose examinations do not come up even to the minimum which the Council has resolved, in the meantime, to accept. To remedy this defect, your Committee would suggest that the Council should recommend—

"1st. That after 1868, all Examinations be removed from the list of those recognized which do not in all respects come up to the minimum which the Council laid down in 1866.

"2nd. That the various Licensing Boards be recommended to discourage the practice of receiving the Certificates of these bodies on certain Branches, and then supplementing their Examinations by others in the omitted Branches.

"3rd. That examinations in Arts, specially designed for Medical Students, should not in any case imply education inferior to that of Students intended for other professions.

"4th. That all examinations in Arts should be conducted by Examiners specially qualified in Arts.

"5th. That it be remitted to the Branch Councils to consider how the means of Examining Medical Students in General Education can be most easily provided at the several seats of Medical Education under their jurisdiction, and to report on this subject to the Council in 1868.

"6th. That it be remitted to the Branch Councils to visit as far as possible the different Preliminary Examinations held by Educational as well as Licensing Bodies, and to report their opinion of these Examinations to the next Meeting of the General Medical Council.

"Since the foregoing Report was prepared, the Council have instructed the Committee to consider and report on a communication addressed to the Council—

"A recommendation in a Memorial from the County and City of Cork Medical Protective Association to the following effect:—

"That the course for a Degree in Arts in the different Universities should, in the opinion of your Memorialists, be preliminary to that for a Degree in Medicine, and that a course of education embodying both Classical Studies and the various branches of Physical Science, should be indispensable before entrance on Medical and Surgical Education of whatever character."

"In regard to that part of the Memorial of the Cork Medical Protective Association, your Committee are of opinion that the Council, having already decided that the Examination on General Education shall be undergone before the Student commences his Medical Studies, and having endeavoured gradually to improve the Preliminary Education, are going, as fast as it is safe to do, in the direction indicated by their Memorialists.

"ALEXANDER WOOD, *Chairman.*"

The Council then entered into a long discussion upon the report, some portions of it being very severely handled—Dr. Andrew Wood, Mr. Rumsey, Sir Dominic Corrigan, Dr. Paget, Dr. Fleming, Dr. Christison, and others—portions of the same being expunged or withdrawn by the consent of the Council, to which the following motions refer:—

Moved by Dr. ALEXANDER WOOD, seconded by Dr. EMBLETON, and agreed to:—

"That in re-issuing the recommendation that 'English Language, including Grammar and Composition,' be one of the subjects of Examination, notes to the following effect should be appended—

"The General Medical Council will not consider any Examination in English sufficient that does not fully test the ability of the Candidate—1st. To write a few sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition. 2nd. To write a portion of an English author

to dictation. 3rd. To explain the grammatical construction of one or two sentences. 4th. To point out the grammatical errors in a sentence ungrammatically composed, and to explain their nature. 5th. To give the derivation and definition of a few English words in common use."

Moved by Dr. ALEX. WOOD, and seconded by Dr. EMBLETON:—

"That in re-issuing the recommendation that 'Latin, including translation and Grammar,' be one of the subjects of Examination, the following notes be appended—

"The Council recommend that in conducting the Latin examination the following rules be observed:—1st. That the candidate, with or without the aid of a dictionary, should be required to translate three or four sentences from an easy author, not having been informed beforehand from what author the sentences will be selected. 2nd. That he should be required to translate easy sentences from English into Latin, either with the aid of a dictionary, or on being furnished with the Latin words, altered in order, number, case, mood, and tense. 3rd. That he should be required to parse a Latin sentence, so as to show his acquaintance with Latin grammar."

With permission of the Council, for the foregoing motion the following was substituted—

1. Moved by Dr. ALEX. WOOD, and seconded by Dr. STORRAR:

"That in re-issuing the recommendations of the Council of 1866, to No. 4, viz., 'Latin, including translation and grammar,' the word 'composition' be added."

The motion was negatived.

2. Moved by Dr. ANDREW WOOD; seconded by Dr. PARKES; and agreed to:

"That after 1868, all Examinations be removed from the list of those recognized which do not in all respects come up to the minimum which the Council laid down in 1866."

3. Moved by Mr. SYME; seconded by Dr. STORRAR; and agreed to:

"That the application from the McGill College, to have their Certificates of Preliminary Examinations recognized by the Council, be acceded to."

4. Moved by Dr. PARKES; seconded by Mr. HARGRAVE; and agreed to:

"That an answer be sent to the Cork Medical Protective Association, to the effect that the Council, having already decided that the Examination in General Education shall be undergone before the Student commences his Medical Studies, and having endeavoured gradually to improve the Preliminary Education, are going as fast as it is safe to do in the direction indicated by the Cork Medical Protective Association."

5. Dr. SHARPEY submitted to the Council the following

"REPORT OF THE FINANCE COMMITTEE.

"The Finance Committee beg leave to present, in the table subjoined, a statement of the estimated and actual income and expenditure of the year 1866; also an estimate of the income from ordinary sources, and of the expenditure, as far as the Committee are able to judge, for the year 1867.

"The expenditure of 1866 has exceeded that of 1865 by £513 1s. 5d. This excess is in considerable part due to an increase in the expense for printing the minutes of Council. The increase of charge over that of the previous year, for attendance at the Executive Committee, is £50 16s.

"From the figures in the table it will appear that the actual income of the past year exceeds the estimate by £53 6s. 9d; but, as on the other hand, the actual expenditure is greater than what was estimated, there is a balance of £455 16s. 11d. against the Council.

"As observed in the Report of last year respecting such estimates, it is scarcely possible to judge of the prospective expenditure with any near approach to accuracy, inasmuch as the amount is greatly dependent on the duration of the

Sessions of Council, which cannot with certainty be determined beforehand.

"A statement of the receipts and disbursements on account of the 'British Pharmacopœia,' since the date of the account presented last year, and of the balance in the Bank to the credit of the General Council, is given up to January, 1867.

"The Committee also present an account of the expense of preparing and publishing the New Edition of the 'Pharmacopœia,' so far as known or estimated, with an estimate of the proceeds of the sale of the entire impression of 20,000 copies.

"BRITISH PHARMACOPŒIA" STATEMENT.

Moved by Dr. STORRAR; seconded by Dr. RUMSEY; and agreed to:

"That the Report of the Finance Committee be adopted."

This concluded the sittings for this day, and the meeting adjourned.

FRIDAY, JUNE 7TH.

The report of the Committee appointed on May 31st to prepare a scheme for the visitation of examinations for the next year, and especially to consider the best means of supervising the Arts Examination, was brought before the Council by the Chairman, Dr. Alexander Wood. This report having been considered on the whole to be satisfactory, it was adopted with but slight modification. We append the report as amended:—

(REPORT.)

"Your Committee report, that by the Medical Act, two methods of Visitation of Examinations are permitted:

"One by the members of Council;

"The other by persons deputed by the Council;

and they presume that a combination of the two would not be contrary either to the spirit or the letter of the Medical Act.

"A Committee appointed by the Council, on this subject, reported in favour of the second of these methods (see Minutes, vol. i., p. 126); but their suggestions were, on the 1st July, 1861, rejected by large majorities in the General Council.

"On the 6th April, 1865, the following motion was agreed to by the Council (Minutes, vol. iii., p. 165):

"That each of the Branch Councils, or such of their members as may be deputed by such councils, shall from time to time, visit the examinations, preliminary as well as professional, conducted by the Qualifying Bodies in their respective divisions of the United Kingdom, and report the results of their observations to the General Council."

"Under this resolution the Branch Councils gave in reports in 1866.

"In 1866 the same plan was continued with this addition, that the visitors were required to include in their re-

ports a statement of the facts observed, and of their opinion of the efficacy of the examinations, as also such remarks and suggestions or defects in them as circumstances may indicate—(Minutes, vol. iv., p. 279.)

“Under this resolution reports have been given in, in 1867, which have been repeatedly admitted, by various members of the Council, to be of great interest and value; and they will, in all probability, be rendered more conducive to the improvement of the examinations by the labours of the Committee appointed by the Council this Session, and which is still sitting.

“Your Committee regret to find that while the Examinations of every Licensing Body in England have been visited and reported on, the reports from Scotland and Ireland are defective; that of Scotland not including any report on the University of St. Andrews, the Royal College of Physicians of Edinburgh, and the Royal College of Surgeons of Edinburgh, although the joint examination held by these bodies is reported on; while from Ireland no report has been given on the examinations of the Apothecaries’ Company.

“After a very full consideration of the subject, your Committee have determined to report that it appears to them desirable to continue the present system for one year longer at least.

“They are, however, of opinion, that each Branch Council should consider how far it is necessary to visit annually the Examinations of each Licensing Body, and whether the labour and expense of conducting these visitations might not be abridged by limiting the visitations of each year to the examinations of certain bodies only.

“In regard to the visitation of the Arts Examinations, the Committee have fully considered the propriety of having it conducted by Special Examiners as well as by mixed boards; they are of opinion, however, on the whole, that such a change is not desirable.”

“That the Visitors of Examinations shall in future receive payment for their services, at the same rate as for attending a meeting of the Branch Council, in addition to travelling expenses.”

“That the expense of visiting the examinations be paid from the funds of the General Council.

“ALEXANDER WOOD, *Chairman.*”

The following report of the Committee on the subjects of professional education was next brought forward and discussed paragraph by paragraph:—

“The Committee appointed to consider and report ‘what are the subjects without a knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered?’ beg to submit the following lists of subjects:—

- “1. ANATOMY.
- “2. GENERAL ANATOMY.
- “3. PHYSIOLOGY.
- “4. CHEMISTRY.
- “5. MATERIA MEDICA.
- “6. PRACTICAL PHARMACY.
- “7. MEDICINE.
- “8. SURGERY.
- “9. MIDWIFERY.
- “10. FORENSIC MEDICINE.

“The Committee in enumerating the subjects a knowledge of which should constitute a minimum of the acquirements possessed by every registered Medical Practitioner desire to add the following explanatory remarks:

“CHEMISTRY should include a knowledge of the principles of Chemistry, and of those details of the science which bear on the study of medicine.

“MEDICINE AND SURGERY should include a knowledge of systematic and clinical Medicine and Surgery, and also of Morbid Anatomy.

“FORENSIC MEDICINE should include a knowledge of Toxicology and of the principles of Hygiene.

“The Committee desire further to recommend that the

knowledge of these subjects should be not only theoretical, but such as can be tested by practical examination.

“RICHARD QUAIN, *Chairman.*”

Dr. QUAIN, as chairman of the committee, considered that but little need be said by him on the report which he had the honour of submitting for the approval of the Council, he would only allude to it in general terms. It being the duty of the Council to determine what were the subjects necessary to be taught a man, before he was competent to exercise his profession as a physician or surgeon, he deemed that those enumerated in the report would not be considered too stringent, and although he did not lay it down as a rule, that a man whose vocation was a physician should be required to know how to cut off a leg or to tie an artery; yet the knowledge he wished to be imparted to all, should be thoroughly practical, and that though a perfect knowledge of the theory of each individual subject should not be enforced, still something of each should be known, that when the practitioner was called in to see a patient in any emergency, as was so often the case, be he physician, surgeon, or apothecary, he should be able to treat the case promptly and efficiently, and he thought that if the recommendations contained in this report were adopted, a great step towards this end would be attained.

Dr. AQUILLA SMITH agreed with what had fallen from Dr. Quain, and deemed the report to be, in the main, eminently satisfactory. There was, however, one omission to which he must object, namely, the all-important subject of botany.

Dr. STORRAR hoped that no objections would be taken to the ten subjects mentioned in the report being made compulsory. They could not possibly pass a milder measure than that proposed, the only question was whether it could not be extended. He considered a knowledge of them to be quite as necessary for a physician as for a surgeon, and *vice versa*. For the examinations at the College of Surgeons, attendance at the lectures on nine out of these ten subjects was enjoined, so that it was not altogether a new thing the Council were asked to sanction; although, he was sorry to say, students who had attended them were not examined as to what benefits they had received thereby, he was, however, pleased to know that even this would soon be required.

Mr. COOPER would give his entire approval to the measures proposed. He would ask how they could think of sending any man forth as duly qualified to practise his profession either in this country or the colonies if he were deficient in any one of these branches.

Mr. HAWKINS thought there were great difficulties in the way of compelling every man to pass examinations on all the subjects contained in the report. There were exceptions, and he premised that, according to the part each intended to adopt as his future profession, he should be more particularly examined on subjects more especially pertaining to that branch.

Mr. RUMSEY begged to introduce his remarks by expressing his satisfaction that the amendment which he was about to propose had been virtually advocated by his old friend, Mr. Cæsar Hawkins, to whom he owed the direction of his early studies in surgery. He also confessed, with much regret, that he was deprived of the support which, he believed, he should have received from Dr. Stokes, whose absence that day, and the cause of it, all so much deplored. His object was to ask the Council to consider the advisableness of retaining what is here called “Forensic Medicine” in their educational programme. He would in the first place briefly notice an error in terminology. “Forensic Medicine” was only a part—even a small part—of legal or public medicine; and he could not conceive that it was intended to give exclusive prominence to that branch of the subject. He would ask, then, ought legal or stale medicines to be included as a necessary subject of professional education and examination for all who were to be admitted on the register. Now, if

it were not intended to include the other branches of public medicine, then by far too little was required; but, if preventive or prophylactic medicine, and the elements of psychological medicine were to be included, then the demand was certainly too great. He saw that, by a subsequent explanation of terms in the Report of the Committee, "Forensic Medicine is to include the principles of hygiene." Now, this was a vast subject, for he presumed the knowledge to be required was not merely such as might be obtained by attending one or two of the courses of lectures given in some universities and medical schools on this subject, but a much wider and deeper understanding of these "Principles of Hygiene." He presumed that it would include a knowledge of the physical sciences, such as is demanded by the London University for its science degrees. It would also include a more minute acquaintance with pathology, human and comparative; also, a practical acquaintance with *vital and sanitary statistics*, and of the true method of using *numbers* in matters of public health. Then, it should also include the study of *medical topography and climates*, i.e., of the external circumstances of the population to be advised for. It would, on all these grounds, involve a more extended knowledge of ætiology, or the causation of disease and mortality. The demand, if inclusive enough, was too great, for the following reasons:—1st. Because, within the age of 21 (the age at which we permit youths to enter the profession), and within the four years of study, which we deem a sufficient period of preparation for practice, so comprehensive a group of subjects could not be properly taught or effectively learnt; 2nd. Because those subjects which are of the greatest practical importance to the general medical practitioner ought to occupy the whole of the period allotted to professional education. To introduce State Medicine into this course, it would have necessarily one of two results—(a.) If the pupil devotes full attention to the ordinary subjects of professional education (all of which he must know before he is turned loose upon the public) he will have no time left to master the great and growing questions included in the terms preventive and legal medicine, and which are not adequately provided for in the present courses of medical education. (b.) If the pupil bestows that careful study to the various branches of public medicine which their importance demand within the period which we have defined for medical education, then he maintained that (unless he be a man of extraordinary power—a sort of Admirable Crichton) he would not have time to prepare, as he ought, for the ordinary work of a curative practitioner. Such, then, were the chief reasons for which he objected to an inclusion, which, if not supplemented by further study and additional examinations, must either end in the grant of a sham qualification, the production of an imperfectly-qualified body of medical jurists and health officers, the frequent performance of medico-legal forces in the courts of justice, and the official supply of fallacious and absurd sanitary advice to local administrative authorities; or it must impair materially the student's chances of attaining a sufficient amount of knowledge in curative medicine and surgery, and in those sciences on which medical practice was necessarily based. He wished not to be misunderstood. By no means did he propose this amendment for the purpose of banishing hygiene and legal medicine from medical education, or of interfering with the laudable efforts which were being made in this direction by many of our universities and great medical schools; but he did it for the purpose of ultimately establishing those studies and qualifications on a more safe and true basis. When the proper time arrives, he was prepared to propose such an extension of our scheme of medical education as would provide for the acquirement of a substantial and trustworthy qualification in hygeiology and legal medicine. He did not assume that they should think of creating a numerous class of such men as Taylor, Christison, and Geoghegan: that would be impossible; but he was ready, if his amendment was carried, to propose that, in order to promote the attainment of

a high qualification in preventive, legal; and psychological medicine, a further period of study in those subjects be required, and that the age of 23 be the earliest age at which any candidate having previously obtained a licence to practise from one of the bodies in schedule (A) should be admitted to examination for a certificate in Public or State Medicine. The public necessities demanded the institution of some such mark and test. A class of men distinguished by special qualifications in these subjects, was necessary, both for the credit of the Profession and for the satisfaction and security of society. There was an increasing demand for men so qualified, by public bodies, by coroners, by courts of law; and the unfitness of the existing body of practitioners had been nobly and candidly confessed by our best authorities. He begged leave to quote from two distinguished living authorities.

"It is obvious that the Profession as a body does not possess these qualifications for the peculiar duties of scientific instructors of the State. To credit the average general practitioner, pure surgeon, or pure physician with such qualifications, would be transparent flattery, for neither the special literature which we possess, nor the requirements of our educating and examining bodies, nor the relations in which the majority of practitioners are placed towards society, afford any means for their attainment."—*Dr. Anstie*.

"The evidence is often of a kind that involves minute investigations, and an exact knowledge of subjects that may not be actually required by a medical man more than once or twice in a life-time, however experienced and eminent he may be as a practitioner. He may have got up the subject thoroughly when going through his academic curriculum, and he may be an old man before he has had to draw upon such knowledge for judicial purposes. It may have been as latent, or unemployed, or well-nigh forgotten, as the processes and foramina of the sphenoid bone, or the reflections of the peritoneum, or as the natural history of some plant in some remote corner of the globe, that furnished some dusty old drug once in favour with doctors. Dr. Symonds added, which of us would like to have to tell all the proofs that an infant had never lived an extra-uterine life."—*Dr. Symonds*.

He might also appeal to one of the illustrious dead, the late Professor Graves of Dublin, whose authority on such a point no one could question:—

"But you are told that you may be called upon to decide questions of medical jurisprudence which demand an accurate knowledge of chemistry; that you will be required to test poisons, and detect them when accidentally or purposely mixed with food or drink. What should you do in such cases? Why, do not undertake any investigations of the kind, refuse to make them, refer them to those who are competent to the task. Where will you find a man engaged in the practice of physic, fully capable of deciding such questions? What practising physician or surgeon is competent to enter at once upon an investigation of this nature? I have lectured some three or four years on medical jurisprudence, and have bestowed a good deal of attention on the subject, and yet if called upon to decide a case of poisoning, I would refuse, and say I was incompetent to the task. What, then, is to be done under such circumstances? This is a matter of deep importance to society. It is of the utmost consequence that the wretch who poisons should not escape, and that the innocent should not suffer. It, therefore, behoves the Government to employ and pay persons capable of deciding such questions. [Here the President—*pro tem.*, Dr. Christison—interrupted Mr. Rumsey by saying that he should be obliged if he would be as brief as he possibly could, as he had already occupied much of the Council's time. Mr. Rumsey said he had but two lines to read when Dr. Christison interrupted, and as he did not often occupy the attention of the Council, and had then spoken but ten minutes, he claimed it as a right to be heard by the Council, and proceeded]—Then, and not till then, will the task be duly performed, and the de-

cisions be such as the public can look up to with respect and confidence."—*Dr. Graves.*

He implored the Council not to stultify their proceedings by requiring impossibilities, and by sanctioning a system of professional employment in public inquiries, which had hitherto inflicted much obloquy on medicine, and caused extreme dissatisfaction and distrust in the public mind.

*Dr. EMBLETON* quite concurred with the remarks that had fallen from *Mr. Hawkins.* He wished to take the broad yet simple view of the question. If a student intended to pursue the vocation of a physician, he should be more particularly examined on those branches which pertained to the clinical practice of medicine; if that of surgery, the various subjects connected with surgery should be more particularly dwelt upon in his examinations. Certainly a knowledge of all these subjects would be essential in either case, and no man should be allowed to go forth as duly qualified unless he possessed this knowledge.

*Dr. APJOHN* would like to see the subject of botany introduced, as he deemed it of greater importance than even forensic medicine.

*Dr. ANDREW WOOD* thought that at first sight the subject did not partake of the importance it deserved. But in effect it challenged the Council whether or not it was necessary for a man to have a knowledge of every one of these branches of education, before he became a qualified practitioner. He held that a man, to be a good physician, must know something of surgery; and a surgeon must also be acquainted with the theory and practice of physics. He knew many had been put on the register merely through the possession of a licence in midwifery, when he had never been tested as to his knowledge of surgery, and the same thing happened every day with licentiates of the Apothecaries' Hall. He contended they were not in a position to admit pure physicians or pure surgeons—they were in the hands of the public, and the public weal must be consulted.

*Dr. FLEMING* said, as he understood the subjects enumerated in the report were to be adopted as the minimum standard, he would support it. But on the subject of forensic medicine he must be permitted to say with *Mr. Rumsey* that it had such a broad scope, that the time allotted to pupils was quite insufficient. It was a study of a life-long character, and he hoped that particular branch of education would not be pressed.

*Sir DOMINIC CORRIGAN* considered the omission of botany a very serious matter. When a man was called in to give evidence upon a case of poisoning, how could he do so unless he understood the poisons of various plants, and the effects exercised by each upon the system.

*Mr. HARGRAVE* hoped that if botany was now on the list of optional subjects, it would be at once transferred to the compulsory list.

*Dr. ALEX. WOOD* said if this list of subjects was to be adopted as the minimum standard, where would the maximum test lead them to? Did the Council mean to infer that because a man was not *au fait* on every one of these subjects he was not fitted to practise? He maintained that the requirements were too stringent, and that if they persisted in drawing the strings too tight, they would assuredly snap asunder. *Dr. Wood* suggested that as there was no immediate necessity for legislation on the point of medical education, but in preliminary study, they should pass the matter to a more convenient time.

*Dr. PARKES* admitted that hygiene was not necessary, but stripped of that the list did not appear to him a very terrible one, and he hoped the Council would adopt it.

*Dr. CHRISTISON* knew that botany was a difficult subject to handle. In the Edinburgh University they required it, absolutely, and he had noticed that it was a subject of all others most liked by students; if it were possible, he would like to see it embraced in the list of compulsory subjects for all bodies. He instanced the fact, that there was a species of belladonna, in appearance much like the common blackberry. Now in this case it

was important that if a child were brought before a medical man he should be able to determine whether the symptoms were those from an overgorging of blackberries or from eating only a few berries of the belladonna plant.

*Dr. QUAIN* then proposed that the report as amended be adopted, which, with the exception of the two last paragraphs, was carried *nem. con.*

The following letter, relating to the case of *Mr. Forman*, was handed to our reporter for publication:—

"*Dr. Alexander Wood* presents his compliments to the President of the General Council of Medical Education and Registration, and begs to hand to him the accompanying letter, which he received this morning from the Secretary of the College of Physicians of Edinburgh—

"Physicians' Hall, Edinburgh, 6th June, 1867.

"MY DEAR WOOD,—I write a line to say that *Forman* has returned his diploma, so that now the College is free from him.—Yours very truly,

"D. R. HALDANE.

"*Dr. A. Wood.*"

SATURDAY, JUNE 8.

The Council resumed its sitting at one o'clock, and proceeded to a consideration of the following report:—

"REPORT OF THE COMMITTEE ON RETURNS FROM THE LICENSING BODIES OF PROFESSIONAL EXAMINATIONS, AND THEIR RESULTS, AND ON THE REGISTRATION OF STUDENTS FOR THE YEAR 1866.

"The Committee beg leave to lay before the Council, a table, compiled from the returns, according to recommendation 6, sect. v. of the recommendations of the General Medical Council of 1866, viz.:—"That returns from the licensing bodies in schedule (A) be made annually, on the 1st of January, to the General Medical Council, stating the number and names of the candidates who have passed their first, as well as their second examinations, and the number of those who have been rejected at the first and second examination respectively."

TABLE.

LICENSING BODIES.	PASSED.		REJECTED.	
	1st Examination Number.	2nd Examination Number.	1st Examination Number.	2nd Examination Number.
R. Coll. Phys. London . .	69	60	22	6

\* By the Regulation, University Candidates are allowed, under certain conditions, to postpone their examination in Physiology until the first M.B. Examination of a subsequent year.

† In this return, those gentlemen having the letter D prefixed to their names in both columns, were Candidates for the Double Qualification in Medicine and Surgery of the Royal College of Physicians and Surgeons of Edinburgh.

‡ Final Examination for M.D. under old regulation.

"It will be observed that returns have been sent in by all the licensing bodies with the exception of the Queen's University in Ireland, from which no return has been received since 1864; and the Committee would therefore suggest that the Registrar of the Council be directed to address a letter to the authorities of the Queen's University in Ireland, requesting them to furnish a return of professional examinations and their results, in accordance with the recommendation of the General Medical Council.

"2. The Committee find that of students registered for the year 1866, there were:—

In England . . . . .	477
„ Scotland . . . . .	302
„ Ireland . . . . .	157
Total . . . . .	936

"The Committee are aware that, owing to imperfections in the registration of 1865, a number of students who commenced professional study in that year were only registered in 1866; but the Committee have not sufficiently accurate information to enable them to state the exact number of such students.

"Of the whole number of students registered in 1866, it appears that 580 passed the preliminary examination in that year. Of the remainder, 208 passed the preliminary examination in 1865, and 146 in previous years.

"The Committee would suggest that a tabular statement of the number of students registered in the three divisions of the kingdom be appended to the list of medical students registered during the year.

"D. EMBLETON, *Chairman.*"

It was moved by Dr. STORRAR, seconded by Dr. SHARPEY, and agreed to, that the report be adopted.

The report of the Committee of Examinations was next brought forward and discussed; but as, in the present stage of the Council, it could not possibly be thoroughly and practically gone into, it was referred to their next meeting. This report is a very voluminous, at the same time a very valuable one, and we hope our space will not preclude its publication in our next, as is the case in the present issue.

Dr. ANDREW WOOD moved, seconded by Dr. PARKES, and agreed to:—

"That the report of the visitation of examinations be received and entered on the minutes, and that the consideration of it be postponed till next session. That, in the meantime, the report be sent to the various licensing bodies, with a statement that it has been drawn up by a committee, but has not yet been considered by the Council, who are desirous, before discussing the suggestions contained in it, to ascertain the opinions of the licensing bodies regarding them."

Mr. CÆSAR HAWKINS moved, seconded by Dr. SMITH, and agreed to:—

"That the Executive Committee be authorized to apply to the licensing bodies for such information as may be necessary for the due execution by the committee of such business as may be delegated to them."

Dr. ARJOHN having expressed his desire to retire from the post of member for Dublin on the Pharmacopœia Committee, Dr. Aquilla Smith was appointed in his stead.

The following motions, by Dr. A. SMITH, were then moved and adopted:—

"That a fifth volume of the Minutes of the General Medical Council, the Executive Committee, and the Branch Councils, with a complete Index, up to the end of the year 1867, be published without any unnecessary delay."

"That the thanks of the Council are due, and are hereby tendered to the Treasurers, Dr. Sharpey and Dr. Quain, for their important services."

"That the thanks of this Council are eminently due, and are hereby offered, to the Royal College of Physicians, London, for their obliging and courteous accommodation during the present session of the Medical Council."

The Registrar was requested to convey this resolution of the Council to the Royal College of Physicians in write, and Dr. Risdon Bennett, as the representative of this College, was asked to bring the same personally before the College at their next sitting.

"That a gratuity of twenty guineas be given to the resident officials of the College of Physicians, for services rendered to the Council."

Dr. SHARPEY in proposing "that gratuities be given, of thirty guineas to Mr. Bell, and twenty-five guineas to Mr. Roope, the Clerks, in consideration of the satisfactory manner in which they have performed their duties, and for their extra trouble in conducting the sale of the new edition of the British Pharmacopœia, bore testimony to the intelligence and zeal that had on all occasions been displayed by those for whom he proposed this gratuity, especially in the sale of the new Pharmacopœia. He had noticed with pleasure the assiduity and care that had been shown by them; and he was convinced, that for the extra trouble, which had devolved upon them on this and other occasions, there would not be a dissentient voice in the Council to vote for them the sum he asked. This having been carried,

Dr. ANDREW WOOD in proposing the last motion, which we need scarcely add was carried with acclamation and genuine enthusiasm, bestowed a very high eulogium on the character of the President, of his talents in Committee of the valuable advice he was wont to give the Council, and last, though not least, of his great courtesy, and efficiency in discharging the onerous duties of that chair:—

"That the thanks of the Council are hereby cordially tendered to the President for his kind, courteous, and efficient services during the present session of the General Medical Council."

The PRESIDENT in reply, begged to thank the Council most sincerely for their kindness in according to him such a vote. He esteemed his position at that Board very highly, and still more that it met with their approbation. If at any time he appeared to them a little severe in his decisions, they must remember that he was always actuated with a desire to facilitate the business of the Council in the various measures brought before them. He begged to make one other observation before they parted. It was his desire that a copy of the new Pharmacopœia should be sent to all the foreign, colonial, and American bodies, that they might see what England was doing in that direction; and, he would further suggest, that each copy be despatched with the edges cut and gilded. This suggestion having been agreed to, the session of the General Medical Council of 1867 closed.

conduct of the Government, and the Council is to be congratulated on the manner in which it repudiated the proposal that it should abdicate its functions by suffering a Secretary of State to decide on the admission or exclusion of certain persons on the Register; it is its first duty, both to the public and profession, jealousy to guard. Never was a more unjustifiable slight offered to such a body, than this cool suggestion of granting the Government authority to review the decisions of the Council. Surely we might as well place ourselves under a paternal despotism at once, as allow a Secretary of State to issue his fiat, giving permission to practice.

If public opinion had not already unmistakably declared that Mr. Ex-Secretary WALPOLE was unfit to fill any official position, the manner in which he attempted to deal with an important department of the public service, and a numerous and learned profession, would have called for our animadversion. It seems to us, however, that the Medical Council have been only unfortunate in the delay which Mr. WALPOLE'S obstructiveness has imposed upon them, and that they may proceed to the discharge of one of their most important functions in pushing forward the Medical Amendments Bill, without the least regard to the latest of the diplomatic stupidities which have rendered Mr. WALPOLE'S official reign a fit epoch for record in the Almanacks.

Having referred Mr. WALPOLE'S letter to a Committee to prepare a reply, the Council occupied itself with a discussion on the revision of standing orders, which, as it possessed no general interest, we took the liberty of curtailing.

Nevertheless, the character of the discussion affords us a text. In every assembly, as a rule, there is a greater or less number of persons, who in the desire to distinguish themselves, and in that poverty of discrimination which does not enable them to find a cue in the legitimate debate, are doubly acute on points of order. They obstruct business at every turn by rising "to order," and render it impossible to discharge business by their efforts to promote regularity. Experience of such interference often prompts the suggestion that in the foundation of societies there should be neither bye-law nor standing order, which, for one occasion that they are useful, are in twenty instances simple impediments.

By a redundancy of such members, the transactions of the Medical Council are like a street block, frequently brought almost to a stand-still, and while the headmost van-driver is fending with the policeman, the long cue of attendant conveyances wait for progress. One is led to wish that we had less zeal for system and regularity, at the risk of occasional blunders and less polished phraseology, with the advantage of more rapid progress of business.

We propose to return to our review of the Council's proceedings next week.

## REPRESENTATIVES OF THE SCOTCH UNIVERSITIES.

SHOULD the present Scotch Reform Bill become law, we sincerely hope that the Profession will make an effort to secure both the University seats. We have already discussed the case of the united Universities of Edinburgh and St. Andrews, and we may add, that during the week several new names have been mentioned as likely candidates. We are also in possession of the names of several Medical Graduates who are prepared to put to the test the power of the Profession to return the member. Some of these, however, think it better to take no step until the bill shall have become law.

Respecting the united Universities of Aberdeen and Glasgow, many rumours are afloat. We believe the lawyers are prepared to contest the seat, besides which the names of merely political personages have been freely mentioned.

We hope that neither will be able to snatch the seat from science, and particularly from medicine. There are many good men and true who would accept the honour among the Medical Graduates of Glasgow and of Aberdeen. Amongst these, we beg to point out one whose claims are considerable, and who would unite local interest to that of the Profession. We allude to Dr. ANDREW CLARK, whose lectures before the London College of Physicians we recently reported. Dr. CLARK is well-known in political as well as professional circles, and has always taken an interest in those questions which the Profession desires to bring before Parliament. He is himself a Graduate of Aberdeen, and his present position in London is such that he has a right to look for such recognition. His name is familiar to the public in connection with the Mansion-house Cholera Committee of last year, as Physician to the London Hospital, and as a warm supporter of Mrs. GLADSTONE'S proposed Convalescent Hospital, which has already received our cordial approbation. The advantages which an influential member resident in London throughout the year might confer on such a constituency need not be pointed out. The Medical Graduates would do well to take steps to secure such a representative as Dr. ANDREW CLARK.

---

## THE RECENT EPIDEMIC IN DUBLIN.

IN our present number we give a considerable portion of the debate at the College of Physicians in Dublin, and next week we hope to conclude this report, and, at the same time, to make some remarks on the subject in our leading columns.

We should have had much pleasure in concluding the report this week, but the necessary publication of the proceedings of the Medical Council, and other matters of passing interest, render this impossible. Meanwhile, we may say that the epidemic in ques-

tion has become a subject of national importance, as only a few days ago, Lord Naas, in his place in the House of Commons, was asked, and had to reply to a pointed question regarding it.

### METROPOLITAN POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THIS Association, which was called into existence last year, has just issued its Quarterly Report, and this fact affords us the opportunity of drawing attention to the proceedings of a society, which has not only been well supported by the Poor-law Medical Officers, but by a large number of hospital physicians and surgeons, who have allowed their names to be placed in the list of honorary members.

The objects of the Association, as set forth in the rules adopted at the first general meeting, in July, 1866, are as follows:—

1. To obtain for the sick poor chargeable to the State, the advantages, in respect of nursing, dietaries, supply of medicines, medical and surgical appliances, cubic and floor space, ventilation, light and general treatment, enjoyed by the sick poor in hospitals and kindred institutions, supported by voluntary contributions."

2. To obtain life appointments for all Poor-law Medical Officers, and entire, instead of partial, payment of salaries from the Consolidated Fund; and thus to secure, at once, due recognition of their position as State servants and greater freedom and independence of action.

3. To provide a basis for consultation and united action, in all cases of difficulty arising out of the nature, and in the discharge of their duties.

4. To obtain an authoritative decision upon all disputed questions relating to duties and extra medical fees.

5. To obtain from the local authorities the provision of all medicines and appliances prescribed for the sick poor, and the employment and payment by the same, of qualified dispensers.

6. To address representations to the Poor-law Board by memorial and deputation, and, if need be, to petition the Legislature in such cases and circumstances as may appear to render such action necessary: and, generally, to provide a channel through which all defects in the Poor-law medical service may be brought to light and discussed with a view to their removal or amelioration.

It may readily be imagined how much of that sort of exertion, described in the 6th clause, has been called for during the last few months. The passage of Mr. Hardy's bill through the House required the constant vigilance of the leaders of the Association; and, though their efforts were not in every instance successful, still, we think, on the whole, they have good reason to be satisfied with their achievements, since they can show a useful result to their labours, and their organisation is eminently calculated to secure to the Poor-law Medical Officers the consideration to which they are entitled. Then again, the Association is not without work in reference to the Vaccination Bill now before Parliament, nor can we conceive anything more desirable than that such a body should take steps to inform the Legislature of their opinions in reference to so difficult a question. The cumbrous machinery of the proposed bill, the inadequate remuneration, the multiplicity of certificates, and so on, are points on which the Council are prepared to act. An opinion is expressed in the quarterly report, that no legislation will be effective that does not provide adequate payment to the vaccinator, efficient inspection, and compulsory prosecution by the inspectors. The amount named as a minimum is 2s. 6d. per case, at the station, and surely no one can pretend that this is too much for the work.

Another question of great importance, and to which we shall again more particularly allude, is the desirability of having uniform dietaries for the several classes in the workhouses.

To this subject the Association has lately devoted a large share of attention. Dietary tables have in fact been cir-

culated freely for suggestions, and a large number of replies having been received, a scheme has been finally settled, and is now being urged on the Poor-law Board.

To the following resolutions which were submitted to Mr. Hardy while president of the board, no reply has at present been received, but they are no doubt engaging the attention of his successor:—

1. That the power of the Medical Officer to order "extras" and comforts for the sick poor should be defined so as to preclude the possibility of future collisions with the Guardians, Managers, &c.

2. That in the interest of the ratepayers and of the Medical Officers provision should be made for a more rigid examination of applicants for sick relief; and, if possible, a definition of those entitled to such relief should be laid down by the Central Board.

3. That an authoritative Pharmacopœia for the metropolis should be issued by the Poor-law Board, in accordance with the practice in voluntary hospitals, so as to facilitate prescribing and inspection.

4. That there should be uniform dietaries for all classes of the poor in the Metropolitan workhouses, hospitals, asylums, and district schools, to be directed by the Poor-law Board.

5. That provision should be made for the establishment, as far as practicable, of a uniform system of management in the dispensaries, the workhouse-hospitals, and the asylums.

To this we may add quotation, showing clearly the work that has been done in the last quarter:—

"Your Council feel that the Association may be fairly congratulated upon the success of Mr. Hardy's Bill. They cannot, however, but regret that the right hon. gentleman, by his removal to another department of the Government, will be unable to carry into effect his own measure—a measure with which his fame as a statesman must be endingly associated. That the Act will confer many and great advantages upon the sick poor, and will tend to improve the position of the medical officers there can be no doubt: but time and experience alone can tell to what extent. The only indications your Council possess, at present, of the probable working of the Act, are to be found in an important joint-report by the metropolitan inspectors, published not long since. This report also reveals the interesting fact that the views of this Association are, in the main, very much in accord with those of the inspectors, who, among other things, advocate uniformity in management of the workhouses and uniformity of dietaries. This latter question is one which has long engaged the attention of your Council, and so far back as September, 1866, they tendered the services of the Association to the Poor-law Board with the view to the formation of a suitable dietary-table for general use in the metropolis. They have deemed the present time opportune for bringing the subject prominently before the Association, in the hope of striking out a scheme which may eventually put an end to the anomaly of the same classes of the poor in the forty workhouses being dieted in as many different ways. This they think may be effected without introducing any extreme changes in the mode in which the inmates have been hitherto dieted."

Now, the propriety of urging the general adoption of a fixed dietary must, to a certain extent, depend on the scale adopted, and this can scarcely fail to give rise to considerable differences of opinion. Yet we may very properly observe that a scheme which has been framed in such a manner as this, and upon which so large a body of professional men has definitively pronounced a favourable opinion, deserves the most careful consideration of all interested in the matter. We therefore add the several dietaries as they have been finally adopted by the Association:—

#### Nos. 1 to 5—HOUSE DIETS.

##### No. 1.—CHILDREN FROM 2 TO 5 YEARS OF AGE.

Breakfast and Supper—4 oz. of bread,  $\frac{1}{2}$  pint of milk, and  $\frac{1}{4}$  oz. of butter.

Dinner	{	Sunday, Tuesday, and Thursday—3 oz. of mutton, and 6 oz. of Potatoes.
		Monday and Friday— $\frac{1}{2}$ pint of scouse or Irish stew, and 2 oz. of bread.
		Wednesday—6 oz. of suet pudding, and $\frac{1}{2}$ oz. of sugar or treacle,
		Saturday—8 oz. of sweetened baked bread pudding.

## No. 2—CHILDREN FROM 5 TO 9 YEARS OF AGE.

- Breakfast*—5 oz. of bread,  $\frac{1}{2}$  pint of milk porridge.
- Dinner*—  
 Sunday, Tuesday, and Thursday—4 oz. of mutton and 8 oz. of potatoes.  
 Monday and Friday— $\frac{3}{4}$  pint of scouse or Irish stew, and 3 oz. of bread.  
 Wednesday—8 oz. of suet pudding, and  $\frac{1}{2}$  oz. of sugar or treacle.  
 Saturday—10 oz. of sweetened baked bread pudding.
- Supper*—5 oz. of bread,  $\frac{1}{2}$  pint of milk, and  $\frac{1}{2}$  oz. of butter.

## No. 3—CHILDREN FROM 9 TO 16 YEARS OF AGE.

- Breakfast*—6 oz. of bread, and 1 pint of milk porridge.
- Dinner*—  
 Sunday, Tuesday, and Thursday—5 oz. of meat and 8 oz. of potatoes.  
 Monday and Friday—1 pint of scouse or Irish stew, and 4 oz. of bread.  
 Wednesday—12 oz. of suet pudding.  
 Saturday—14 oz. of sweetened baked bread pudding.
- Supper*—5 oz. of bread, and  $\frac{1}{2}$  pint of milk, and  $\frac{1}{2}$  oz. of butter.

## No. 4—ABLE-BODIED INMATES FROM 16 TO 60 YEARS OF AGE.

- Breakfast*—  
 Men: 6 oz. of bread, and  $1\frac{1}{2}$  pints of oatmeal porridge.  
 Women: 6 oz. of bread, and 1 pint of porridge or sweetened tea.
- Dinner*—  
 Sunday, Tuesday, and Thursday—5 oz. of meat, and 12 oz. of potatoes.  
 Monday and Friday— $1\frac{1}{2}$  pints of pea or barley soup, and 4 oz. of bread.  
 Wednesday and Saturday—12 oz. of suet pudding.
- Supper*—  
 Sunday, Tuesday, and Thursday—6 oz. of bread, and  $1\frac{1}{2}$  pints of broth.  
 Men and Women } Monday; Wednesday, Friday, and Saturday—6 oz. of bread, and  $1\frac{1}{2}$  oz. of cheese, or  $\frac{1}{2}$  oz. of butter, and  $\frac{1}{2}$  pint of broth.

## No. 5—INFIRM INMATES, INMATES OF INFIRM WARDS, AND ALL INMATES 60 YEARS OF AGE AND UPWARDS.

- Breakfast and Supper*—5 oz. of bread, 1 pint of sweetened tea (with or without milk as preferred), and  $\frac{1}{2}$  oz. of butter.
- Dinner*—  
 Sunday, Tuesday, Wednesday, Thursday, and Saturday—4 oz. of mutton, and 8 oz. of potatoes.  
 Monday and Friday—1 pint of scouse or Irish stew, and 4 oz. of bread,  $\frac{1}{2}$  pint of porter (or ale) daily.

## Nos. 6 to 10—SICK DIETS.

## Nos. 6 to 9.

- Breakfast and Supper*—5 oz. of bread, 1 pint of sweetened tea (with or without milk) and  $\frac{1}{2}$  oz. of butter.
- Dinner*, No. 6—4 oz. of mutton, 8 oz. of potatoes, and  $\frac{1}{2}$  pint of porter.
- „ No. 7—6 oz. of mutton, 12 oz. of potatoes, and 1 pint of porter.
- „ No. 8—8 oz. of cooked fish, and 8 oz. of potatoes.
- „ No. 9—1 pint of beef-tea, and 4 oz. of bread (and 1 pint of arrowroot, at night.)

## No. 10—MILK DIET.

- Breakfast*—3 oz. of bread, and  $\frac{3}{4}$  pint of milk.
- Dinner*—3 oz. of bread, and 1 pint of milk.
- Supper*—2 oz. of rice, and  $\frac{3}{4}$  pint of milk.

The sick diets Nos. 6 to 10, together with mutton chops, eggs, light pudding (custard and rice) to be included in an *ad libitum* diet for special cases, as directed by the Medical Officer.

Casuals and refractories to have the uniform diet prescribed by the Poor-law Board.

Lunatics to have, according to circumstances, No. 5 or No. 7 diet, or, generally, any of the diets (Nos. 4 to 10), at the discretion of the Medical Officer.

Children under 2 years of age to be dieted at the discretion of the Medical Officer.

Suckling women to have No. 5 diet. (Beef or mutton on meat days).

It would be found economical to use only legs and shoulders of mutton for the sick, aged, infirm, and young children. The children should have roast meat at least once in each week, and the sick and infirm twice or thrice.

The allowance of meat to be reckoned free from bone and after cooking.

The broth should be thickened with rice or pearl barley, and properly flavoured with herbs, vegetables, &c.

The beef-tea should be made exclusively from lean beef, and

all fat should be carefully skimmed off before serving. Each inmate should be allowed to add condiments to taste.

The arrowroot should be made with milk (1 pint to the  $\frac{1}{2}$  oz. and 1 oz. of sugar). This food might, as a rule, be served by the night nurses.

The tea should be served, to each ward, in a tin vessel of adequate capacity, provided with lid and tap. The milk should not be added before serving. The tea must not be boiled. There would be no objection to each inmate of the sick and infirm wards having a weekly allowance of dry tea and sugar, and it would be much preferred by them.

The bread for the sick and infirm should be served to the nurses of each ward in loaves, and not in allowances, for each inmate separately. Thereby great waste of bread would be avoided.

Arrangements should be made for serving the food in a hot state. There should be a separate kitchen for cooking the sick diets.

The porter should be of the best quality.

An occasional dinner of bacon: and the occasional substitution of cabbage and other vegetables, for potatoes, would be an agreeable and beneficial change, and is strongly recommended.

All measures to be of the Imperial standard.

“Extras,” wines, spirits, &c., for the sick, to be specially ordered by the Medical Officer.

Details of quantities and ingredients for making the scouse, &c., have been intentionally omitted. The principle of uniformity once accepted, these can be readily supplied.

## Notes on Current Topics.

**BRITISH PHARMACOPEIA.**—We understand that up to the close of last week the sale of this book had reached 9000 copies. This, coming so soon after the failure to force the circulation of the former edition, looks well for the prospect of the new one being generally adopted. Our readers will, no doubt, in future prescribe according to the new national work.

**THE CONVALESCENT HOSPITAL.**—As intimated in our last number, a report was current that Her Majesty had been pleased to apply half a million sterling, part of the accumulation in the privy purse during her retirement from public life, to the building and endowment of a Convalescent Asylum. Having doubts as to its accuracy, we simply gave the report and the paragraph from the *Standard* confirming it. We were not surprised to see in the *Times* and other papers a distinct contradiction; no one duly considering the position of the younger members of the Royal family, their connections by marriage, &c., &c., could expect so large a sum to be taken from the privy purse, notwithstanding Her Majesty's well-known desire to promote the happiness of her poorer subjects.

**CHOLERA.**—We regret to say that last week a decided case of cholera was admitted to the London Hospital under the care of Dr. Ramskill. We have also heard that more cases have been received into the Paris Hospitals. Is it not time to be at work?

**A DOCTOR THREATENING TO SHOOT A LAWYER.**—A warrant was issued for the apprehension of Mr. J. Stringfield, Surgeon at Weston-super-mare, who was brought before Mr. Knox at Marlborough-street, charged with feloniously and maliciously sending a letter threatening to kill Mr. W. Watkins, the chief partner in the firm of Watkins, Baker, and Bayliss, solicitors, No. 11, Sackville-street. The letter, which was read at the request of the prisoner, is a singular one. It seems that an unfortunate disagreement arose between him and his wife soon

after their marriage, and that at length proceedings were commenced in the Divorce Court at the instance of the wife. Mr. Watkins is her legal adviser, and the letter charges him with having taken advantage of a woman not of strong character, with having unduly influenced, and indirectly coerced her to conceal herself, and with having employed the writer's own servants and others to steal his three children, and gives him notice that if he (the writer) cannot have access to his children within a reasonable time he will shoot him. Mr. Knox said the peculiar character of the letter rendered it a proper matter of inquiry whether the writer was in his right mind or not, and though he expressed his sorrow for having written it, he was remanded by order of the Magistrate, that his state of mind might be inquired into.

**A GOOD EXAMPLE.**—Mr. Rumsey, whose name was familiar as an authority upon state medicine before he was appointed by the Crown to a seat on the Medical Council, has just set an excellent example by presenting some valuable relics to corporations likely to preserve them. He has given to the Royal College of Physicians of London a copy of Dr. Fordyce's manuscript lectures; and to the Royal College of Surgeons of England a set of MSS. volumes, containing the lectures of Hunter, Baillie, and Cruikshank. These lectures were taken in shorthand, and then written out by the father of Mr. Rumsey. The two Royal Colleges in London thus acquire for their libraries mementoes which cannot fail to be highly prized.

**THE COUNCIL AT APOTHECARIES' HALL.**—Among the great functions of the General Medical Council, which has just concluded its labours, it was but right that it should fulfil the noble one of dining. Not less appropriate was it for the corporation, which is the city guild of the medical bodies, should exercise the hospitality on the occasion. The worshipful company of apothecaries of London provided a very excellent dinner in their Hall, over which, we are happy to say that a unanimity prevailed which has never been equalled in the sittings in Pall Mall.

**MASKS AND FACES.**—Under this title Mr. Ernst Shulz is now giving in London an entertainment to which our attention has been directed by a learned *confrere*, as interesting in a Physiognomical point of view. Mr. Shulz amuses his auditors by rapidly exchanging the expression of his countenance so as to personate all varieties of character in turn. The command he has attained over the muscles concerned in facial expression is certainly astonishing, and as the newspapers generally have accepted the entertainment as something decidedly novel, and all London Society has been to see it, we can scarcely do otherwise than mention this feature of the performance. It illustrates, in a very remarkable manner, to how large an extent the expression of the human face depends upon muscular action and may be brought into complete subjection to the will. What can the physiognomists say to this?

**THE EMPRESS CHARLOTTE.**—It is stated in the *Gazette de France* that the Medical attendants of the Empress Charlotte have declared, as the result of their consultation, that their unhappy patient will never recover her reason, and that her life will be one of very short duration.

**THE PRINCESS OF WALES** is going on favourably; her general health is good, and the knee slowly improving.

## ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE twenty-fifth annual meeting of this Society was held at four o'clock on Monday week in the Albert Hall of the Royal College of Surgeons,

Dr. BUTCHER in the Chair.

Amongst those present were—Drs. Churchill, M'Clin-tock, Guinness, Sharkey, Evory Kennedy, J. Harvey, Daly, Darley, R. P. Walshe, Brady, Stewart, Siphorpe, Macnamara, M'Donnell, Moore, Vice-President of the College of Physicians; Bredon, Athill, Quinan, Mackesy, Benson, Duke, J. R. Kirkpatrick, Hamerton, J. F. Duncan, J. H. Benson, Beatty, Baxter, Minchin, Wharton, Osprey, Halahan, Hanrahan, M'Dowell, Bennett, Mollan, H. G. Croly, Johnston, H. Kennedy, Tufnell, Flanery, Greene, Fitzpatrick, Cronyn, Thorpe, Gustace, Maguire, Robert Tate, Chaplin, Thomas Davis, Manorhamilton; Nugent, Duncan, Grimshaw, Armstrong, Bradshaw, Croker, Denham, Coulton, White, Hagan, Kidd, A. Walshe, and Stoker.

THE CHAIRMAN said—Gentlemen, it gives me very sincere pleasure that one of my last official duties as President of the Royal College of Surgeons is to preside on this occasion of the annual meeting of the Royal Medical Benevolent Fund Society of Ireland. I say duties, because I am satisfied that no member of our profession, who fairly examines the claims of this valuable Society, but will feel it a duty no less than a privilege to do what he can to promote its interests. Whether we consider the objects which it proposes to itself, the amount of good which it has already effected, or the future benefits which it is calculated to confer under each and all of these aspects, this Society commends itself to our sober judgment, our heart's sympathy, and our cordial support. It was established for a twofold purpose; first, to "assist our professional brethren when struggling under the pressure of disease or other calamities;" and secondly, to "administer relief, under circumstances of peculiar urgency and distress, to the widow or family of a professional man whom death had removed." The members of our profession are, like those in every other walk of life, liable to calamities and reverses which no prudence can guard against, no foresight can avert. They are, moreover, from the very nature of their avocations, exposed in a peculiar degree to disease in all its varied forms. The records of our profession—the very list of applications for relief from the widows and orphans of deceased medical men contained in the last year's report of this Society, as well as in that of the present—show how frequently those whose office it is to minister to the bodily sufferings of others are themselves struck down, and become the victims of the diseases with which they are brought into contact. The need, therefore, of such a society as this is so obvious and so urgent that it is only wonderful some effort to establish it was not made long ago. The progress which the Society has made during the twenty-five years of its existence is at once a proof that it supplies a great and acknowledged want, and an omen, I trust, of growing prosperity and increased usefulness for the future. The report, which will be presently submitted to you, will exhibit the exact condition of the Society's finances at the present moment. The Society, as most of you are aware—constituted in May, 1842—began to distribute grants, in money, in the year 1848; so that this will be the twentieth year of distribution of grants. Over nine thousand pounds, including the present distributions, have been given in grants since 1848. In the present year there is the largest number of applicants, even so great as eighty-five; but I am happy to say there is the largest amount available, and to be distributed—about eight hundred and fifty pounds. And now let me speak home to each of your hearts. Among the claimants this year are ten medical men in dire destitution, through age or disease, who are to receive sums varying from six to thirty pounds each; and on the list for the present year are sixty-two widows, having in all one hundred and eighty-four children. On over-

looking very carefully the report, I find that the management and working of the Society has been conducted in the most economical manner, almost the only expenses being for printing, postage, and collecting. The funded money of the Society, I am happy to tell you, amounts to the sum of £12,000. The objects of this Society being then so excellent in themselves, its achieved results so beneficial, its prospects so hopeful, it needs no argument to prove that it deserves and demands the support of every member of our profession. In the list of its supporters are found the names of many generous donors who do not belong to our profession, but who yet feel that the public at large ought to share in alleviating the distresses of those to whom in the hour of sickness and pain all turn for relief. At the head of that list stands the name of our august patroness, our beloved Queen, and that of the lamented Prince Consort. To particularise other names would be invidious. I shall only add that I am sure the contributions from the general public would be much increased if the members of our own profession as a body evinced more interest in the welfare of this Society than, it must be confessed, they at present do. It is hard to expect that others will feel for us that sympathy which we ourselves do not exhibit, or that they will be zealous on our behalf if we are cold and indifferent ourselves. No maxim is truer than this—"Help yourselves and others will help you too." I will now, Mr. Treasurer, present to you my donation of one hundred pounds for this most valuable Society. (Loud applause.) I will not detain you any longer, gentlemen, but will call on the Secretary to read the report.

The Chairman then, amid applause, handed the Secretary his donation of £100.

Dr. M'Clintock read the report, which appeared in our last issue.

Dr. BEATTY moved the adoption of the report and statement of accounts. He said the report was commendable, as it was the first time the Council were able to make a laudatory statement regarding the funds of the Society. This gratifying fact arose out of the gift of their ever-to-be-revered and beloved *confreere*, Dr. Carmichael, who also never lost sight, while alive, of the interests of the institution. The report stated that the amount to be distributed amongst the recipients was considerably more than in former years. He liked the word "considerably," because it showed they were enabled to act more liberally. The sum given to the recipients would be increased, which was a matter of congratulation to them all. The accounts received from the branches were likewise most gratifying. He (Dr. Beatty) regretted that the Committee were not aware that the President intended to have given the munificent subscription which he had announced that day, for they would have taken notice of it in their report. It was a subscription which entitled him to their gratitude, and he trusted that the special thanks of that meeting would be awarded to him.

Dr. MACKESY, in seconding the resolution, observed that he could add but little to what had been said by Dr. Beatty, who had displayed on that occasion the philanthropy, good feeling, and warmth, which always marked his character. It was to be regretted that there should be any apathy amongst their professional brethren in supporting that charitable institution, which was so very deserving of assistance. He was convinced, however, that the more its objects became known, the more would subscriptions to it be increased. He conceived that every medical man who received a salary would, if he considered the matter, give some subscription to show his good feeling.

The resolution was then adopted.

Dr. EVORY KENNEDY moved a vote of thanks to the various branches in the provinces for their continued exertions on behalf of the Society. He congratulated the Society on the success which had attended it that year. There were 79 applications answered favourably in sums varying from £5 to £35. The example of their President was worthy of imitation by gentlemen occupying a high position in the profession, and he would suggest that the

future Presidents of the College of Surgeons and the College of Physicians should give, at least, half as much as the Chairman had done.

Dr. GREENE seconded the motion, which was adopted.

Dr. JOHNSON, Kilkenny, proposed a vote of thanks to the morning papers and several provincial journals for the important services which they had rendered to the society.

Dr. MOLLAN seconded the resolution, which was put and carried.

Dr. CHAPLIN proposed the appointment of the central committee for the ensuing year.

Dr. CROKER seconded the resolution, which was agreed to.

Dr. TUFNELL proposed the next resolution, empowering the trustees to invest the funds of the society in such securities as they might think advisable. He observed that by withdrawing their funds from the three per cents. and investing them in Bank Stocks, or East Indian Stocks, they would derive a larger income and be enabled to act more liberally.

Dr. DUNCAN seconded the resolution, which was then adopted.

Dr. MACKESY was then called to the second chair, and a warm vote of thanks was passed to Dr. Butcher for his dignified conduct while presiding, and for his handsome donation, after which the meeting separated.

#### FOURTEENTH ANNUAL MEETING OF THE IRISH MEDICAL ASSOCIATION.

THE annual meeting of the members of this Association took place on Monday week, in the Hall of the Royal College of Surgeons,

Dr. MACKESY in the chair.

There was a large attendance, and amongst those present were—Drs. Quinan, Ledwith, O'Rorke, M'Iver, Ardel, Mason, Marks, Ledwith, Kingstown; Beatty, Morrough, H.M. Madras; Jacob, Maryborough; Thornhill, M'Clintock, Walsh, Kinahan, Armstrong, Hanrahan, Mackesy, Martin, Johnson, Mapother, Darby, Darley, Bodkin, Tuam; Chaplin, Brassington, Labatt, Macnamara, Sharkey, Bradshaw, Greene, Walsh, Smythe, Purefoy, Quinlan, Hethringham, O'Brien, Slewin, Longford; Jacob, Davis, Hayden, Benson, Carte, Tufnell, Shannon, H. T. Croly, Gogarty, O'Farrell, Coulton, Wharton, Benson, jun.; Maurice Collis, Chapman, Grimshaw, Murdock, &c.

The CHAIRMAN said he was happy to see so many familiar faces around him upon this occasion. The report prepared by their zealous and excellent secretary, Dr. Quinan, gave admirable information on the various concerns of the Society, and left very little for him to say. He believed that this Association was the first public body that called the attention of the General Medical Council to the necessity of students having a proper preliminary education; and this was done at a meeting held in 1865. The views contained in the resolution passed at that meeting had been so generally adopted by the Council recently that he could not but congratulate the Association upon having given a tone to the Medical Profession of the United Kingdom upon this important subject. He then read the report, which appeared in our supplement last week.

Dr. ALBERT WALSH said the duty devolved upon him of moving the adoption of the report so ably drawn up by their indefatigable Secretary. The first point of importance to which it referred, was the necessity for superannuation allowances for dispensary medical officers, who had become worn out in the public service. This was a matter of great importance to the profession, and he urged on them all to use their exertions collectively and individually in every proper way, and to use their influence with Members of Parliament, with the view of having this measure of justice granted. The only fund to which at present dispensary medical officers could apply, after they had

been worn out in the discharge of their duties, was the Medical Benevolent Fund. The utmost that, however, could grant, was only £30 a-year, and that was a very poor thing for the family of such a man to look to. The next point was with respect to medical witnesses. Their Secretary had waited in reference to this matter upon the public officer at the Castle, and upon Mr. Collis, the rating master, who was the son of the late Professor Collis. That gentleman was certainly anxious that medical officers of dispensaries should be properly compensated upon such occasions. Having referred to some other matters of detail relating to the affairs of the Society, he concluded by moving the adoption of the report.

Dr. DARBY seconded the motion. He stated that the question of superannuation was one of great importance to the profession. Men in high official position had objected to it on the ground that medical officers of dispensaries did not give their entire time to the public service, and that it was a rule of the Treasury to give superannuations only in such cases; but he contended that dispensary medical officers had more of their time engaged in the discharge of their duties than many officers in various departments of the public service. The dispensary medical officer was always at his post, and it was erroneous to say that they were not entitled to receive superannuation because they did not give their whole time to their dispensary. He thought that if they worked together and pressed this matter properly they would secure simple justice. Besides, these medical officers had spent the best of their lives in the service of the public, and he urged that the interests of the poor were largely involved, for if superannuation were not granted, the result would be that men having nothing to look to for their support but their salaries, would continue to hold their positions longer than they were physically able to do so. As to the question of consultation fees, he had been for years in the habit of calling in the assistance of his brother medical men, and the Board of Guardians had never refused to pay the fee. He was of opinion that the Poor-law Commissioners, especially the Medical Commissioners, were entitled to their best thanks. It was stated that the police in various parts of the country were issuing tickets for dispensary medical assistance, but it was a very great mistake to suppose that the police had legally any such power. Dr. Darby concluded by paying a warm tribute of regard to the memory of Dr. Bannon.

Dr. PUREFOY mentioned that he had been summoned by visiting tickets issued by policemen to attend upon cases of assault, &c. He had also known books of tickets to be placed in the hands of railway officials. These proceedings were contrary to the Medical Charities' Act.

Dr. D. JACOB mentioned an instance in which he had, with considerable difficulty, established a principle of a consultation fee being allowed.

Dr. HANRAHAN stated that he had been frustrated in an effort to establish the principle of consultation fees for brother medical men.

Dr. A. H. JACOB entered into some details respecting a proposition to make the MEDICAL PRESS the organ of the Association, and after some remarks from Dr. Chaplin, of Kildare, and Dr. O'Rorke, of Enniscorthy, the report was adopted.

Dr. ARMSTRONG moved the next resolution as follows:— "That we persevere in our efforts to procure a retiring allowance, or a compensation for poor-law and dispensary medical officers when incapacitated by old age or loss of health in the performance of their duties as public servants."

He contended that it was not fair to object to the granting of superannuation on the ground that dispensary officers had an opportunity of supplementing their salaries by private practice. He mentioned a number of instances of public servants who had similar opportunities of supplementing their official salaries, and who gave less time to the public than dispensary officers. He impressed upon the Association the necessity of using every means in their power to accomplish this great object.

Dr. QUINAN read a form of petition to Parliament, which had already, he said, been circulated and presented to Parliament.

Dr. DARLEY seconded the resolution. He referred to the fact that half the salaries of medical officers had been recently charged upon the Consolidated Fund, and a great obstacle in their way heretofore in inducing Boards of Guardians to accept the principle of superannuation was the fact that the whole of the salaries were charged upon the poor rates. Now that the law was so very materially altered in this important respect, it would greatly facilitate their future exertions in this point. Referring to the question of tickets, he said the Board of Guardians were entitled to appoint wardens, who were thereby legally qualified to distribute tickets applying for medical help, but he pronounced it an unwarrantable and improper proceeding, as well as a great hardship, to oblige the medical officers to attend upon tickets issued in the way mentioned.

The resolution was put and carried.

Dr. JACOB moved the third resolution as follows:—

"That the Medical Reform Act, as carried out by the Medical Council has failed in securing for the Medical Profession the advantages originally intended, and that no adequate return has been given for the expenses incurred. We, therefore, suggest that a *uniform curriculum* of high preliminary education and of professional and scientific study be adopted for all licensing bodies, empowered under the act to grant licenses or diplomas in medicine or surgery, as the best means of maintaining the respectability and status of the profession, and of securing to the public competent practitioners in medicine and surgery."

He dwelt upon the necessity and importance of a good preliminary education on the part of persons seeking to join the profession. He regretted to say that many of the village doctors of Ireland were not so educated and qualified as to raise the status of the profession. He also complained that a medical man, a member of the Association, had written to a public body offering to discharge the duties of medical officer for nothing.

Dr. COLLIS seconded the resolution. As a clinical teacher he said he found his most laborious efforts to impart instruction to some of the young gentlemen who came before him futile, owing to their inability to take in and put together two ideas. The powers of memory, comparison, and observation, were what all cultivated. He was afraid, however, that the matter resolved itself into a question of money, and the best class of young men adopted more promising professions.

The resolution was put and carried.

Dr. MARTIN, of Portlaw, said it was but fair that they should have some regard to the interest of their professional brethren in the army and navy. He felt a deep interest in it because he had a son in the service and another going into it. He regretted to say that the suggestions made by the late committee of inquiry into the department had not been carried out to the fullest extent. From a return made to the House of Commons it appeared there were 697 assistant-surgeons in the British army, and he regretted to say that promotion in the service was extremely slow. The profession should, therefore, endeavour in every way they possibly could to assist them and advocate their claims. After a service of twenty-five years it was but fair that they should get a reasonable retiring pension. He moved a resolution to the effect that it was to be regretted that the suggestions of the committee on the state of the medical service in the army and navy have not been carried out with a view of providing a proper retiring allowance for the army medical officers, and affording promotion after a certain amount of service, as such was the only course by which they could secure the service of qualified medical men. It was important that the army should have the services of qualified medical men, especially when serving abroad, when they could obtain the services only of the medical officer of the regiment.

Dr. MOROUGH seconded the resolution.

The resolution was put from the chair and adopted, the Chairman observing that, as an old Medical Officer, he had much pleasure in putting the resolution.

Dr. MARTIN then moved a resolution to the effect that the portrait of the late Dr. Kinsley, of Roscrea, the founder of the Medical Benevolent Fund Association, should be placed in a better position than it at present occupied in the College of Surgeons. His memory was deserving of some memorial.

Dr. BRADSHAW, of Bansa, seconded the motion, which was adopted.

Dr. SMITH, of Castletown, moved a resolution to the effect that the present unsatisfactory state of the law with regard to the remuneration of medical witnesses summoned by the Crown rendered it desirable that one uniform scale of payment should be adopted. They were entitled to two guineas fee for attendance in a court of justice, and reasonable expenses.

Dr. DARBY, of Bray, explained the principle on which the law courts acted in reference to the payment of medical witnesses. Every medical man was bound to give evidence for one guinea, who had to come only ten miles, but if beyond that he was entitled to three guineas.

Dr. SMITH said that on poor-law investigations and constabulary investigations medical men were liable to be examined without any remuneration being given, which had occurred to himself.

Dr. BRADSHAW seconded the resolution, which was adopted.

Dr. QUINAN stated he had an interview with one of the taxing-officers of the higher courts on the subject. He had informed him that the judges had determined on a scale of fees, which, though not actually legal, was at present the practice. It allowed two guineas a-day to strangers coming to give evidence, and one guinea with hotel expenses and first-class travelling fare. In the sessions court the arrangement was different, as the matter lay with police and castle authorities. There was at present a Bill before Parliament for the regulation of fees, and it was to be hoped the scheme would be satisfactorily settled.

Dr. MOROUGH moved a vote of thanks to the Poor-law Commissioners for having come to the rescue of dispensary medical officers with regard to the miserable pay offered by the different boards of guardians to dispensary doctors for the zealous and devoted performance of their duty in the late outbreak of cholera. It was one of the first instances in which the Poor-law Commissioners threw the shield of their protection over the medical officers.

On the motion of Dr. DARBY, the officers for the ensuing year were appointed, Dr. Mackesy as president.

Dr. ARMSTRONG moved a resolution in reference to the necessity of Parliamentary legislation for the medical profession. Continued experience proved the paramount importance of Parliamentary representation for the profession, and that the council be requested to take immediate action on the subject.

Dr. LEDWITH, of Kingstown, seconded the resolution, which was adopted.

A vote of thanks was passed to the press.

Dr. MOROUGH having been called to the second chair, a vote of thanks was passed to Dr. Mackesy.

The meeting then separated.

## KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

### SECOND QUARTERLY EXAMINATION, 1867.

#### SECOND DAY.

##### PRACTICE OF MEDICINE.

Dr. W. MOORE, Vice-President.

1. Describe the disease termed Diphtheria, and the form of paralysis which occasionally supervenes.
2. Symptoms, physical signs, and pathology of cerebro-spinal Meningitis?

3. Symptoms, physical signs, and pathology of acute pericarditis?

4. What are the symptoms, physical signs, and the most generally received pathology of the disease termed "Exophthalmic Goitre?"

5. Describe the eruptions met with in typhus and typhoid fevers respectively.

##### MIDWIFERY.

Dr. JENNINGS, Censor.

1. Describe the foetal circulation; and explain why, during intra-uterine life, the left lobe of the liver is larger than the right.

2. Describe the pathology of the disease termed "cyanosis," its symptoms, and result.

3. Enumerate the various means and agents for inducing uterine action.

4. Enumerate, in their ordinary order of origin, the symptoms of pregnancy; classify them, and state which are the most valuable.

5. Describe the management of the third stage of labour; give also the possible causes of delay, and the treatment suited to each.

##### MATERIA MEDICA AND MEDICAL JURISPRUDENCE.

Dr. BELCHER, Censor.

1. Enumerate the "Glycerina" of the Pharmacopœia (1867); their respective compositions, and therapeutic uses.

2. What is Kamala? Give its therapeutic use, dose, and mode of administration.

3. Write a Latin prescription, with directions for use, in words at full length, and without symbols, for an eight-ounce diuretic mixture for an adult.

4. What conditions and diseases are sometimes mistaken for pregnancy; and how would you distinguish them from it?

5. Enumerate the symptoms and appearances of poisoning by Hydrocyanic Acid; and state the quantity required to destroy life.

##### PRACTICE OF MEDICINE.

Dr. GORDON, Censor.

1. What are the symptoms and physical signs of acute tuberculosis?

2. What diseases is it most liable to be mistaken for?

3. What are the symptoms produced by the passage of a gall stone; and how would you treat them?

4. Give the symptoms, effects, and treatment of pertussis.

5. What is the pathology of "Addison's disease," and what are its symptoms?

## SECOND QUARTERLY EXAMINATION FOR LICENSES IN MIDWIFERY.

##### MIDWIFERY, &C.

Dr. RINGLAND.

1. Specify the several axes of the pelvis.

2. Enumerate the various planes of the pelvis engaged in parturition.

3. Contrast presentations of hand and foot; and state the respective diagnosis and treatment.

4. Define the several terms—menstruation, amenorrhœa, dysmenorrhœa, and menorrhagia.

5. In displacements of the uterus, what is the difference between versions and flexions?

##### MIDWIFERY.

Dr. JOHNSTON.

1. At what period of natural labour is assistance required? Describe the nature of that assistance.

2. In which stage of tedious labour is danger to the mother most to be apprehended, and why?

3. Under what circumstances is the employment of the forceps warranted; and what are the particulars necessary to be ascertained prior to their application?

4. Describe the method of using the forceps when the head is low down in the pelvis, and what are the precautions to be observed in order to prevent injury either to mother or child?

5. What are the symptoms which, during labour, would lead to the suspicion that rupture of the uterus might take place; and what would the treatment be under the circumstances?

MEETING OF THE  
GENERAL MEDICAL COUNCIL  
OF EDUCATION AND REGISTRATION.

(Continued from page 545.)

MONDAY, JUNE 3.

THE following report from the Pharmacopœia Committee was read :—

"The Pharmacopœia Committee, in completing the duty assigned to them, have to report that, in accordance with the resolution of the Council, May 26, 1866, the Pharmacopœia was submitted to each Member of the Council on Feb. 1, 1867; that the final revision of the Pharmacopœia was completed at the end of March during the present year; and that the revised copy was forthwith placed in the hands of the Executive Committee, by whom the work has since been issued to the public.

"The Committee beg to report that in the progress of the work they have endeavoured to limit the expenditure on its production, so far as was consistent with its completeness, its accuracy, and perfection. The amount of this expenditure has been £676, 14s., composed of the following items :—

Editors, . . . . .	£550	0	0
Pharmaceutical investigations, . . . . .	100	0	0
Expenses of attendance of Member of Committee for Ireland, . . . . .	25	4	0
Postages, Messengers, Parcels, French Codex, &c., . . . . .	1	10	0
Total, . . . . .	£676	14	0

"The Committee, reminding the Council that the sum of £300 was placed at their disposal in 1865, have now to ask that the Treasurers be authorized to pay the further sum of £376, 14s.

"Having thus brought their labours to a close, the Committee have the satisfaction of testifying to the very valuable services rendered by Professor Redwood in the preparation of the work, to his zeal and his ability, not less than to the readiness with which he gave attention to the suggestions and recommendations of the Committee. They have also to acknowledge the valuable assistance rendered by Mr. Warrington, so far as the state of his health enabled him to co-operate with the Committee; acknowledgments are further gladly offered by the Committee, for the assistance afforded them in the revision of the work, not only by Members of the Council, but also by the several eminent scientific gentlemen to whom the work was submitted before its publication.

"The Committee feel that it will not be thought inconsistent with their duty, to indicate the plan which seems to them the most desirable for watching over the progress of pharmacy, and for making such additions and corrections as would facilitate hereafter the preparation of the next edition of the British Pharmacopœia.

"They would therefore suggest that a Committee, constituted like the present, should be appointed for the purpose just indicated, and that the sum of £50 be placed annually at their disposal to enable them to obtain such assistance as they might think necessary.

May 31, 1867. "R. CHRISTISON, Chairman."

It was stated by the Registrar, that about 7000 copies of the work had been sold within a few weeks, the entire edition printed being 20,000.

Dr. ANDREW WOOD moved, Dr. A. SMITH seconded, which was agreed to :—

"That a sum of £500 be voted to the Members of the Pharmacopœia Committee for their great services in preparing the Edition of the British Pharmacopœia for 1867."

It was then moved by Sir D. J. CORRIGAN, seconded by Mr. HAWKINS, and agreed to :—

"That letters be addressed to the University of Melbourne, the University of Calcutta, the University of Sydney, and the Registrar of the Medical Council of Upper Canada,

informing them that at present it is not legally in the power of the General Medical Council to recognize Colonial Degrees, but that an amended Medical Bill is now engaging the attention of the General Medical Council, and that the recognition of the Colonial Degrees and Licences referred to shall receive full consideration."

A petition was read from Mr. Richard Organ, whose case has been so often before the Council, and who had been struck off the register in consequence of having fraudulently obtained his diploma, to be allowed to present himself for examination at one of the examining bodies.

In reference to this petition, Dr. STORRAR moved, and Sir D. J. CORRIGAN seconded :—

"That the Council, having considered the application of Mr. Richard Organ, see no cause to alter their decision of the 19th May, 1866."

The following amendment was then moved by Mr. HARGRAVE, and seconded by Mr. RUMSEY :—

"That as Mr. Richard Organ has confessed his improper conduct, and as he has repeatedly thrown himself on the leniency and clemency of the Council, he be permitted to present himself for examination before one of the licensing bodies."

The amendment was negatived.

Second amendment, moved by Dr. THOMSON, and seconded by Dr. ACLAND :—

"That the application of Mr. Richard Organ, together with the accompanying documents, be referred to a Committee, to examine and report upon to the Council."

The Committee to consist of Dr. Thomson, chairman; Dr. Acland; Dr. Embleton; Dr. Alexander Wood; Mr. Syne; Dr. A. Smith. The amendment was carried, and, having been put as a substantive motion, was agreed to.

A motion by Dr. PAGET—

"That the application of a medical student for registration, be accompanied by a certificate of his place of medical study."

Having been put to the vote and negatived, the Council adjourned their sittings at six o'clock.

TUESDAY, JUNE 4.

The Council having resumed its sittings at the usual hour,

The President laid before the Council a letter which he had received from Mr. Walpole, in answer to the application that had been made to him, which was as follows :—

"Balmoral, June 1, 1867.

"MY DEAR SIR,—I have just received your communication from the Medical Council, respecting the Amendment of the Medical Act.

"As I am no longer the Home Secretary, and, in point of fact, am not likely to be in London for some days, I have thought it best to send your communication on at once to Mr. Hardy.—Yours ever very faithfully,

"(Signed) S. H. WALPOLE.

"To Dr. BURTOWS."

Dr. ACLAND suggested that, as no time should be lost in bringing the matter before Her Majesty's Government, he would propose—

"That the President be requested to ask Mr. Gathorne Hardy to appoint a time for receiving a deputation from the Medical Council, with respect to the Medical Act."

This having been assented to, the President quitted the chair—returning again shortly—to inform the Council that Mr. Secretary Hardy had consented to receive a deputation from the Council on Thursday at half-past twelve o'clock.

Dr. ACLAND then rose, pursuant to notice, to propose the following motion, which was seconded by Dr. STOKES :—

"That it is desirable that the General Medical Council shall have power to combine with any of the Licensing Bodies mentioned in Schedule (A) of the Medical Act, in conducting Examinations, by the appointment of Assessors, Visitors, or Examiners, conjointly with such bodies, in such number and with such duties as shall be agreed upon

between the Council and the bodies agreeing to conduct such joint examination; that the examiners, assessors, or visitors so appointed shall not be members of the Council, and shall be paid in such manner and at such rate as the General Council, subject to the approval of the Treasury, shall decide; that the qualification so conferred may be entered in the *Medical Register*; that if the qualification so conferred shall be granted after examinations in medicine, in surgery, and in midwifery, it may be accepted by any public bodies who have heretofore required a so-called 'double qualification;' that nothing in this qualification shall debar the holder from obtaining the further title of Physician, Surgeon, Doctor, Master in Surgery, or Fellow of any College, or the like, on such terms as the bodies mentioned in schedule (A) respectively may determine; nor from obtaining separate qualifications from such bodies, as at present."

Dr. Acland introduced the foregoing motion in a most able and elaborate speech, stating his opinions of the absolute necessity that some such measure should be adopted, as it would be of immeasurable benefit to the licensing bodies and the profession at large. Our space being limited, and the proposal having been deferred for a future occasion, we must refrain from introducing the speeches made till this important subject shall again occupy the attention of the Council.

The proposal of Dr. Acland was then superseded by the following amendment moved by Mr. RUMSEY, and seconded by Dr. LEET:—

"That a Committee be appointed to consider the motion of Dr. Acland, and report thereon to the Council at or before their next Session."

The amendment was carried, and the Council adjourned at the usual hour.

WEDNESDAY, JUNE 5.

Dr. PAGET rose, pursuant to notice, to propose the following motion:—

"To adopt the following amendment of clause XI. of Medical Acts Amendment Bill, proposed by Medical Acts Amendment Committee:—

"It shall be lawful for the General Council, by special orders, to dispense with such provisions of the Medical Acts, or with such part of any regulations made by authority of the said Acts, as to them shall seem fit, in favour of persons who shall make application to be registered under the said Acts on Foreign or Colonial Diplomas or Degrees: provided such persons shall have resided in the United Kingdom for a period of not less than twelve months immediately previous to making application to be registered: provided the holders of those Diplomas or Degrees have the right to practise Medicine and Surgery in the countries where they have been granted: and provided the Council shall receive satisfactory evidence that those Degrees or Diplomas, or Licences to practise, have been granted after a course of study and examinations such as to secure the possession by persons obtaining them of the requisite knowledge and skill for the practice of their profession."

He thought this clause might be divided into three parts. First, that it would give those gentlemen now in England, possessing Foreign or Colonial Diplomas, the opportunity of presenting themselves to be registered, and if found worthy, be permitted to enjoy the same privileges as those now practising as duly qualified practitioners. The second part of the clause, being but a repetition of the provision proposed by Sir George Grey, when he was Home Secretary, it would not be conceived, opened the door for any irregularities, by allowing those in the possession of other Diplomas than those obtained through the Licensing Bodies of Great Britain, to be put on the Register, whether they were deserving or not, as it was a well-known fact that, although the possession of these Foreign Diplomas was a warrant for the teaching of medicine, it did not necessarily give the holders the privilege to practice, unless they had gone through the proper course of study and examination; and this he considered to be one great protective measure

gained. Thirdly—He thought the Council were alone capable of judging who was worthy to be placed upon the Register, and they would certainly not accord this privilege to any man, no matter with what degree he might be in possession of, unless they received satisfactory evidence that the degrees or diplomas had been granted him after a proper course of study and examination. He would therefore propose the adoption of the report as it stood.

Mr. CÆSAR HAWKINS begged to second the motion. He thought it was the best way of meeting the question that had been so often raised. The original proposal of Sir George Grey was exceedingly objectionable, and one which they could not possibly adopt. The present Government having imposed upon them the necessity of introducing a measure for the admission of those in possession of a Foreign or Colonial Diploma to the Register before the new Medical Bill could become law, he thought the proposed clause by Dr. Paget a very admirable one, and he had therefore great pleasure in seconding it.

Sir DOMINIC CORRIGAN was very sorry he must rise to oppose this measure. Dr. Paget had stated that it would be impossible for Foreign Graduates to pass the examinations here, and that therefore we must give them other facilities, in order to allow them to the practice of Medicine and Surgery. Now, he (Sir Dominic) maintained that this was the very reason why the clause was objectionable, as it gave facilities for foreigners to come over here and obtain a licence, with but little trouble, on account of the liberality of our system, whilst to the young men of our own country it said as much—"You go over to any of the little petty Universities of Germany—the journey will only cost you about £3; you can there obtain all you want for a very small sum—for they were much in want of money in Germany, and the degrees can be purchased with little or no examination whatever. You can then return home, be received by us, and placed on the Register as a properly-qualified medical man." He thought it possible, that if the present clause, at least the latter part of it, passed, the whole of the licensing bodies might enter into a conspiracy not to recognise a foreign diploma of any kind. He contended there was a great distinction to be drawn between the words, *foreign* and *colonial*, and he would, therefore, treat them in separate clauses. They had abundant opportunity of ascertaining what the colonial diplomas were, they well knew them to be genuine; they were acquainted with the mode of examinations pursued in such Universities as Melbourne, Montreal, &c., and there was consequently but little cause of fear to be apprehended by the admission of colonials to the Register. But with foreign it was a totally different thing; the Council had no means of ascertaining how these diplomas had been obtained, or under what circumstances they had been granted; they could not possibly arrive at the conclusion that the examinations had been honestly conducted, unless they sent over a commissioner to each in order to ascertain the real state of the case; and, even then, it might be contrary to the laws of the country to admit of such enquiries. They did not know the laws of foreign countries; they had no control over the Universities of those countries—if therefore they gave foreigners the privileges which, in their respective countries, were denied to Englishmen, they conferred on them a position and a rank they had never had before, absolutely allowing them to hold public appointments which they could not obtain at home.

Sir Dominic continued—Suppose we take the Universities of Germany, where they were as thick as mushrooms, or America, where they were so numerous that their numbers were unknown, what were the diplomas obtained at these places worth? Why, if they excepted such as those of Berlin, Vienna, and one or two others, they were not worth a straw; and he maintained that if the Council gave its sanction to the resolution proposed, at least in its present form, it would stamp the whole of our licensing bodies with degradation.

(For continuation, see Supplement.)

## Correspondence.

### ST. ANDREWS GRADUATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

MR. EDITOR.—Allow me to notice a mistake which you have inadvertently fallen into in your leading article, in your last number, regarding the Medical Graduates of St. Andrews University. The strict and searching examination of medical candidates was instituted and acted upon subsequent to the appointment of the late Dr. John Reid, a very eminent anatomist and physiologist, to the Professorship of Medicine in the University of St. Andrews, and during his whole incumbency, and was continued after Dr. Day became his successor. No doubt Dr. Day very successfully managed to rouse a great increase in the number of applicants for the degree, who may perhaps boast of being "*Day's Graduates*," but the character of the examination was secured by the University appointing additional qualified examiners from the Lecturers of the Colleges of Physicians and Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and of the Andersonian Institution, from which bodies they are still selected by the University Court. I cordially support the views you have advanced, and trust that the "St. Andrews Graduates' Association" may succeed in getting an alteration in the restriction to 1863 as in the Bill, and that "all medical graduates who have passed a sufficient medical examination since 1840, or who shall still pass such an examination, irrespective of residence, shall be entitled to be registered as members of the University General Council, and as such entitled to vote for the representative in Parliament."—I am, &c.,

W. M.

### THE LATE ELECTION AT THE ROYAL COLLEGE OF SURGEONS, IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your impression of the 5th inst., under the heading "The Election of Council of the Royal College of Surgeons of Ireland," a passage occurs which (most unintentionally, I am sure, does me but scant justice with reference to my recent candidature for the Vice-Presidency of the College. The passage I allude to runs thus:—"For the Presidency, Mr. Adams and Mr. J. Hamilton competed, while for the Vice-Chair, Mr. Porter offered himself. Mr. Macnamara also had laid his pretensions to the Vice-Chair before the electors, but subsequently withdrew from his candidature." Now, although all the Fellows of the College (through a circular issued by me to them) are aware of the full facts, still, as many of your readers, not being Fellows, and, consequently, not having had addressed to them my circular letter, most likely are still in ignorance of the full particulars of the case, you would oblige me by giving insertion to the enclosed letter, a copy of which each elector received *before the day of election*.

Next year (*D.V.*) I purpose placing my pretensions before the Fellows of the College for their consideration, and from the numerous kind communications, both written and oral, that I have received from a great number of them both previous and subsequent to the last election, I entertain no doubt of my claims receiving more than their due share of attention at their hands.—Very faithfully yours,

RAWDON MACNAMARA.

[COPY OF CIRCULAR LETTER.]

MY DEAR SIR,—On Tuesday last I did myself the honour of forwarding you a card, announcing my intention to seek the post of Vice-President of the College of Surgeons. I think it due to you, as to myself, to explain the circumstances under which I sought that distinction at your hands, and why it is that I am now resolved *not* to go forward in my canvass.

On the death of my deeply lamented friend, Dr. Awly Banon, V.P. of the College, being announced, Mr. Porter put down his name on the College list for the *Presidency* instead of the Vice-Presidency of the College, the post for which he had been previously canvassing, and I then put down my name for the Vice-Presidency. Since then Mr. Porter has seen fit to change his mind, and is now again a candidate for the *Vice-Presidency*; and as it would be the last thing that would enter my mind to contest the office with my old and valued friend and colleague, I have removed my name from the list of candidates for the post, and shall feel only too satisfied if you deem me worthy of re-election, on Monday next, to the office of one of your Council.—Your obliged and grateful servant,

RAWDON MACNAMARA.

### THE DANGERS OF INJUDICIOUS BATHING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the bathing season has now commenced, a few words of caution on the subject may be of great service, if you will kindly allow me to suggest, through your columns, a very simple means of preventing the great risk to health and life so constantly incurred, through ignorant and injudicious bathing.

It is a matter which would seem to come properly within the province of the local Sanitary Committees, to take all necessary means to guard from such dangers, those persons who crowd our coasts during the summer months, for the purpose of sea-bathing.

It is a fact too little known, that to bathe without suitable precaution, is to hazard the most imminent peril. Any one who could be so reckless as to place himself voluntarily under the wheels of a vehicle in motion, would be properly regarded as insane; but the folly of the act is not less in those persons who complacently plunge into a bath soon after partaking of a full meal, thus risking sudden death from congestion, or some other fatal mischief. Numbers of bathers who escape a calamity of that description, are nevertheless sufferers from their imprudent mode of immersion; shiverings, headaches, and other symptoms, often succeed the use of the bath, yet the true cause is rarely suspected; probably the bather perseveres with the cold bath, under the vague impression that it may prove a remedy for those unpleasant sensations, which it is all the time increasing.

My suggestion is this—Let notices, headed "Caution to Bathers," be put up in a conspicuous spot, near all bathing-places. The notices should contain the following hints and suggestions:—"It is requested that no person will bathe within two hours after partaking of a meal. It is desirable that all persons should consult their medical adviser before taking a sea bath, as to the need or benefit of doing so."

Notices of this description might also be hung up in all bathing machines.

The bath attendants should be well instructed upon the laws of hygienic bathing.

The cost of such a plan would be very insignificant, considering the benefits likely to result from its adoption. A season never passes without furnishing numerous instances of the risks incurred in consequence of ignorant and injudicious bathing. A case of the kind was reported last week; it occurred in a public bath. A young man, after swimming a short distance, was observed to lose consciousness, and upon medical aid arriving, life was pronounced extinct. "Apoplexy" was said to be the cause of the fatal result; but, if enquiry had been pushed further, "imprudent bathing" might have been shown to have induced the seizure.—I am, sir, yours obediently,

SANITAS.

P.S.—These "hints" might have a wider usefulness, if the daily and weekly press would kindly reprint them, for the benefit of general readers.

### "THE OUTCAST."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reading an article, "The Outcast," in your *CIRCULAR*, I could not help being struck with the soundness of your suggestions, and I think if they could be carried out, a great diminution of sickness, poverty and crime, would be the happy results.

These poor deserted little street arabs are indeed a misery to themselves, and a perpetual curse to society. Having no home and no friendly hand to guide them, they commence at an early age to beg or steal for their existence, and soon grow up to be desperate ruffians and adult thieves.

Residing in a densely populated neighbourhood, near the docks, I am more acquainted with the hovels of misery and crime which abound, than my more fortunate professional brethren at the west end, and I can therefore speak from personal experience on the subject. When we remember there are at least 20,000 of these little pests wandering about the streets of London alone in filth and rags, and oftentimes with disease which communicates itself wherever they go, it does indeed seem more than ever necessary that immediate steps should be taken in order to ameliorate their present sufferings and conduce to their future welfare, by initiating some such a movement, as suggested in your remarks.

Much good has resulted by Ragged Schools and Refuges, and my experience in these matters induce me to remark that, as I have found the majority brought together in this way have not sunk so far below the level of civilization, as to be incapable of good impressions, I think if this movement could be

so far extended as to be made compulsory in the way you suggest, much sickness and still more vice would be prevented. I always find, in my professional capacity, easy access can be gained even to the lowest haunts of vagabondism. The "Doctor" is with them a necessity, upon whom they look as a friend when the "Parson" is denied admittance. And I therefore think that were we to put our shoulders to the wheel, our chances of success would not be remote.—I have the honour to be, sir, yours, &c.

W. U.

## Medical News.

At a congregation held at Oxford, on the 7th inst., the following degree was conferred—M.D., *comitatis causa*, George Frederick Elliott, Trinity College, Dublin.

**THE CASE OF JORDAN.**—At the Marlborough-street Police-court, on Tuesday, Jordan was fined £20 *pro forma* under a summons taken out by the Royal College of Physicians, Edinburgh.

**COD LIVER OLEINE—FOR HOSPITAL USE.**—Messrs. Bedford Brothers, whose Oleine we recently noticed, have made arrangements which will enable them to supply hospitals and other public charities with a cheaper article of the kind. The Cod Liver Oleine for hospital use is stated to differ from the so-called Crystal Cod Liver Oleine, inasmuch as it contains a little more solid fatty matter. No doubt many gentlemen in hospital practice will make a trial of the article, and the profession will thus be placed in possession of facts respecting its value.

**CRINOLINE AGAIN.**—Mr. Humphreys, the coroner, held an inquest on Thursday on the body of a woman aged twenty-one years, who lost her life through wearing crinoline. She approached within a moderate distance of the fire to put some fuel on, but the crinoline had so distended her dress that it caught fire.

**ROYAL ZOOLOGICAL SOCIETY OF IRELAND.**—The Society's Gardens, now in their most beautiful garb of Spring foliage, attracted, during the week ending on Thursday last, more than four thousand visitors. On Sunday the grounds and houses were crowded with sightseers. The Council of the Society have purchased a male and female Wallaly Kangaroo, which, with their young one, are now in the Gardens, and form a principal attraction. The little stranger has only just made its public appearance, though it was born about eight months ago, during which period it has been carried by the mother within her mammary pouch. The Kangaroo is a native of Australia, and many efforts have been made to acclimatise it in Europe, with varying success. The hind feet are very large, and armed with long and powerful toes. With these members the animal, when hunted, bounds along in enormous jumps, and, if overtaken, defends itself, often killing dogs with a single blow. The fore-legs are remarkably small, and are principally used for seizing its food. The Kangaroo may be said to have a fifth leg, for it possesses a very large and muscular tail, on which, it sits when at rest, as a milk-maid does on her milking-stool, and which, in progression, serves as a rudder to direct the animal's movements. The young are produced in an extremely imperfect state, and remain for eight months after birth within a pouch attached to the maternal source of nourishment. The baby Kangaroo now at the Gardens, has just emerged from its shelter, and, as seen hopping in and out of its lodging, is an object of great interest. The Society has also received within the week three very fine Rheas, presented by Arthur Healy, Esq., L.K.Q.C.P.I., and two South American Partridge, the gift of William Kemmis, Esq.

### NOTICES TO CORRESPONDENTS.

The extent of our condensed Report of the Proceedings of the General Medical Council, and of the transactions of the King and Queen's College of Physicians, obliges us to postpone the following communications:—Letter from *Dr. Mackesy* to the Director General of the Army Medical Department, and Reply.—*Dr. Richardson's* Lecture on the Influence of Cold on the Nervous Functions.—Leading Article on the Appointment of Medical Attendant to the Mountjoy Prison.—*Dr. Little*, Case of Epilepsy.—*Dr. H. M. Jones*, Case of Retained Placenta.—*Dr. Peables*, Case of Hydatid of the Liver.—*Dr. McCormac* on the Production of Anæsthesia by the Vapour of Absolute Alcohol.—Investigations respecting Arterial Dilatation, and Result of Nervous Irritation.—*Mr. Denis Phelan*, Letters on a Poor-law Medical Annuity Fund.—Several Letters, Reviews, &c.

*H. W.*—We cannot insert your letter without some proof of the facts stated being placed in our hands.

*Dr. Chapman.*—Your valuable letter in reference to the one on the Treatment of Ague by Heat to the Spine, is unavoidably postponed.

*Dr. C. A.*—We cannot insert the article.

*F. R. S.*—Your communication has been handed to the person named.

### SYRUP OF QUININE.

*Mr. Beckett*, of Heywood, Manchester, has forwarded us a bottle of his Syrup of Quinine and Orange. It is a clear syrup, with the taste of Quinine and Orange Peel, slightly acidulated, and professes to contain two grains of the disulphate in each ounce. The usual tests showed that the specimen sent contained the full quantity.

### MEDICAL APPOINTMENTS.

**ALLT.**—Nathaniel W. Allt, L.R.C.S.I., L.K.Q.C.P.I., &c., has been appointed Acting House-Surgeon to the Royal South Hants Infirmary, Southampton, in the absence of W. Burt Shorto, Esq.

**BELLAMY.**—Edward Bellamy, F.R.C.S. (Exam.) Demonstrator of Anatomy, Charing-cross Hospital, has been appointed Surgeon to the St. George's and St. James's Dispensary.

**BUCHANAN.**—G. Buchanan, M.A., M.B., M.C., has been appointed Demonstrator of Anatomy in the University of Glasgow.

**CARTER.**—A. E. Carter, L.R.C.S.I., L.R.C.P.E., Senior Resident Surgeon of the Northern Dispensary, Liverpool, has been appointed Assistant Medical Officer to the Toxteth Workhouse, Liverpool.

**HARDING.**—T. H. G. Harding, L.D.S.R.C.S.E., has been elected Surgeon-Dentist, to the Islington Dispensary.

**JACKSON.**—Hughings Jackson, M.D., has been elected Physician to the Hospital for the Epileptic and Paralysed, in the room of Dr. Sieveking, resigned.

**MASON.**—James Mason, M.D., M.R.C.S. and L.M., and L.S.A., has been elected Surgeon-Accoucheur to the Sheffield Public Hospital and Dispensary, *vice* Samuel Lawton, M.R.C.S. and L.S.A., deceased.

**ORTON.**—F. Orton, M.B., has been appointed Resident Medical Officer at St. Mary's Hospital, Manchester.

**OSBORNE.**—H. Osborne, M.D., has been appointed Physician to the Islington Dispensary.

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

**BARNES.**—On the 4th inst., the wife of J. W. Barnes, F.R.C.S., of Perry-hill, Sydenham, prematurely of a daughter.

**BUTLER.**—On the 25th ult., at 183, Commercial-road, Newport, Monmouthshire, the wife of John Butler, Esq., L.R.C.S.I., and L.R.C.P.E., of a daughter.

**CHAMBERS.**—On the 3rd inst., at 22b, Brooke-street, Grosvenor-square, the wife of Dr. T. King Chambers, of a daughter.

**FEGEN.**—On the 3rd inst., at 6, St. Jean d'Acre-terrace, Stoke, Davenport, the wife of W. B. Fegen, staff-surgeon, R.N., H.M.S. *Impregnable*, of a son.

**WEAVER.**—On the 1st inst., at Frodsham, Cheshire, the wife of F. P. Weaver, M.D., of a daughter.

**WILSON.**—On the 27th ult., at 6, Montpellier-terrace, Cheltenham, the wife of E. T. Wilson, M.B. Oxon., of a daughter.

### MARRIAGE.

**HARRISON—BOXER.**—On the 23rd ult., at Lancaster-gate Church, Bayswater, J. B. Harrison, M.B., to Roberta Spencer Thomson, fourth daughter of the late Admiral Boxer.

### DEATHS.

**RANKING.**—On the 3rd inst., W. H. Ranking, M.D., late of Norwich, aged 53.

**FFOLIOTT.**—On the 6th inst., at Kilworth, of a severe illness contracted in the discharge of his medical duties, Francis Ffolliott, Esq., M.D., F.R.C.S.I. Dr. Ffolliott was descended from Baron Ffolliott, who was one of the barons that compelled John to sign the Magna Charta, and his family resided for many centuries at Pyrton, in Worcestershire.

### COD LIVER OLEINE FOR HOSPITAL USE.

**BEDFORD BROTHERS**, believing that a pure, good and Cheap Cod Liver Oil is one of the great necessities of Hospital practice of the present day, have arranged to supply the demand in the form of a Cod Liver Oleine.

The Cod Liver Oleine for Hospital use, differs only from the Crystal Cod Liver Oleine imported by Bedford Brothers, and now so generally used amongst the wealthier classes, in that it contains a little solid fatty matter, but not sufficient to interfere with its ready digestion.

The Hospital Cod Liver Oleine, like the Crystal Cod Liver Oleine, is tasteless and inodorous.

In Tins, each 15 or 30 gallons (for Hospitals only), at 6s. per gallon.

87, Tower Hill, London, E.C.,

27th May, 1867.

### UNIVERSITY LIFE ASSURANCE SOCIETY. EXTENSION TO FOUNDATION SCHOOLS.

Additions in 1866 at the rate of 1½ per cent. per annum.

CHARLES McCABE, Secretary.

24, Suffolk-street, London, S.W.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

**FIRST PART OR PRIMARY PROFESSIONAL EXAMINATION FOR THE LICENCE.**—The next Examination of Students who have completed Two Years of Professional Study at a recognised Medical School will commence on Tuesday, July 2nd.

**SECOND PART OR PASS EXAMINATION.**—An Examination of gentlemen who are eligible for admission to the second Examination for the Licence will commence on Tuesday, July 9th.

Registered Medical Practitioners qualified before January, 1861, are admitted to Examination under Special Bye-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all certificates and testimonials required by the Bye-laws are to be left at the same time.

Pall-Mall East, 1867. H. A. PITMAN, M.D., Registrar.

**NATIONAL ORTHOPÆDIC HOSPITAL.**

**L**ECTURES ON DEFORMITIES will be Delivered on consecutive Tuesdays, at 4 P.M., commencing May 21st, as follows:—

On Angular Curvature of the Spine. By Mr. T. Carr Jackson.

On Infantile Osteo-malacia. By Dr. Dick.

On Talipes Varus. By Mr. L. Stromeayer Little.

Free to Practitioners and Students of Medicine.

Hospital, Great Portland-street, London. W.

W. C. HARVEY, Hon. Sec.

**A**pothecaries' Hall of Ireland, 40 Mary-street. The following new Medicines and Preparations are manufactured in the Laboratory on the premises, and a supply constantly on hand:—

THE NEW PREPARATIONS OF THE PHARMACOPŒIA, 1867.

TICHBORNE'S VESICATING COLLODION.

Dr. Richardson's Styptic Colloid; Syrup of Phosphate of Iron, Quina, and Strychnia; Chlorate of Quina; Perchloric Acid; Carbolic Acid, pure and crude (the latter free from Sulphuretted Hydrogen).

ESTABLISHED 1848.

MEDICAL TRANSFER AND PROFESSIONAL AGENCY.

50, Lincoln's-inn-fields, W.C.

**Mr. J. Baxter Langley, M.R.C.S., F.L.S.,**

&c. (KING'S COLL.) has now upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements, and no expense incurred (except in special cases) unless a negotiation be completed.

The general Partnership and Commercial Agency business till recently conducted by him at his City offices, and his experience in his management of large commercial undertakings, combined with his professional acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on all matters of dispute between professional men Mr. Langley has had great experience, and can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation.

Mr. Langley can refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers, and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

**M**edical Assistants. — Wanted immediately, several competent In-door and Out-door Assistants, qualified and unqualified, for town and Country. No charge for registration, but references in all cases required.—Apply to Mr. Langley as above.

**C**ompetent Assistants provided without delay, free of expense to the principals. No gentleman recommended whose antecedents have not been inquired into.—Apply to Mr. Langley, as above.

**F**or Varicose Veins and Weakness. **SURGICAL ELASTIC STOCKINGS AND KNEE-CAPS**, pervious, light in texture, and **INEXPENSIVE**, yielding an efficient and unvarying support, under any temperature, without the trouble of Lacing or Bandaging. Likewise, a strong low-priced article for Hospitals and the Working Classes.

**ABDOMINAL SUPPORTING BELTS**, those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with **EXTREME LIGHTNESS**—a point hitherto little attended to.

Instructions for measurement and prices on application, and the articles sent by post from the Manufacturers,

**POPE & PLANTE,**

WATERLOO-PLACE, PALL-MALL, LONDON.

The Profession, Trade, and Hospitals supplied.

UNIVERSITY OF LONDON.

**N**OTICE IS HEREBY GIVEN, that the next Half-yearly Examination for MATRICULATION in this University will commence on MONDAY, the 24th of JUNE, 1867. In addition to the Metropolitan Examination, Provincial Examinations will be held at St. Cuthbert's College, Ushaw; Stonyhurst College; St. Patrick's College, Carlow; Owens College, Manchester; and Queen's College, Liverpool.

Every Candidate is required to transmit his Certificate of Age, to the Registrar (Burlington House, London, W.) at least fourteen days before the commencement of the Examination.

Candidates who pass the Matriculation Examination are entitled to proceed to the Degrees conferred by the University in Arts, Laws, Science, and Medicine. This Examination is accepted (1) by the Council of Military Education in lieu of the Entrance Examination otherwise imposed on Candidates for admission to the Royal Military College at Sandhurst; and (2) by the College of Surgeons in lieu of the Preliminary Examination otherwise imposed on Candidates for its Fellowship. It is also among those Examinations of which some one must be passed (1) by every Medical Student on commencing his professional duties; and (2) by every person entering upon Articles of Clerkship to an Attorney,—any such person matriculating in the First Division being entitled to exemption from one year's service.

WILLIAM B. CARPENTER, M.D., Registrar.

May 31st, 1867.

**URGENT APPEAL.**

**T**HE Trustees of the Fund which is being raised for the relief of a Medical Man in the West of Ireland (who labours under paralysis, and has Ten young children to support), thankfully acknowledges the receipt of the following contributions, transmitted to them by Dr. McMunn, of Sligo,—in addition to a considerable sum which he collected from non-professional friends:—

Dr. McMunn, Sligo	£5 0 0
Dr. Christian, London	2 2 0
Dr. Lynn, Sligo	2 0 0
Dr. O'Farrell, Boyle	1 0 6
Dr. Harrison, Roscommon, per Dr. O'Farrell	1 0 0
Dr. Fry, Boyle, per Dr. O'Farrell	0 10 0
Dr. Denning, Sligo	1 0 0
Dr. Thompson, Dromahair	1 0 0
Dr. Davis, Manorbhamilton (Second Subscription)	1 0 0
Dr. McMunn, Ballymote	1 0 0
Dr. McMunn, Dromore West	1 0 0
Dr. McMunn, Skreen	1 0 0
Dr. Wood, Sligo	2 0 0
Dr. Hamilton, Carney	1 0 0
Dr. Powell, Sligo	1 0 0
Dr. Longhead, Sligo	1 1 0
Dr. Armstrong, Collooney	1 0 0
Dr. Crean, Brewood, Stafford	1 0 0
Dr. Wood, London	1 1 0
Dr. McDermott, Bath	1 0 6
Dr. Chambers, Deputy Inspector of Hospitals, Halifax N.S.	5 0 0
Dr. J. W. Longhead, 56th Regiment	1 0 0
Dr. J. F. Longhead, Staff Assistant Surgeon	2 0 0
Dr. Murray, Tobercurry	1 0 0
Dr. Wood, Staff Surgeon, Folkestown	1 0 0

£36 14 0

Further Contributions will be thankfully received by the Trustees, Dr. Benson, Captain Hamilton, and George Beamish, Esq., or at the Office of the MEDICAL PRESS AND CIRCULAR.

**TESTIMONIAL TO DR. RICHARDSON.**

CHAIRMAN:

JAMES PAGET, Esq., F.R.S.

HONORARY TREASURERS:

Henry Day, Esq., M.D., Stafford; Francis Sibson, Esq., M.D., F.R.S., 40, Lower Brook-street, W.

BANKERS:

Messrs. Stevenson, Salt, and Co., Stafford, and 20, Lombard-street, E.C.

**A**T a Large and Influential Meeting of the Medical Profession, held at 37, Soho-square, on THURSDAY, August 2, 1866, James Paget, Esq., F.R.S., in the Chair, it was unanimously agreed that a Committee should be formed for the purpose of raising a Testimonial to Dr. Richardson, in recognition of his labours and discoveries in the Medical and Allied Sciences. It was further agreed that the entire Committee be empowered to receive Subscriptions from the Members of the Profession and the community in any part of the world who may be desirous of taking part in the Testimonial. It was further considered best that the Testimonial should take such a form as to be not only in recognition of what Dr. Richardson has already done, but a substantial means for encouraging him to pursue those scientific researches which are so useful to the Profession and the public at large.

HONORARY SECRETARIES—R. Dunn, Esq., F.R.C.S., 31 Norfolk-street, W.C.; R. William Dunn, Esq., 13, Surrey-street, W.C.

ESTABLISHED 1812.

**F**or the Sale of Leeches and all kinds of MEDICAL HERBS. H. POTTERS, Depot, 65, Farringdon-street, London, E.C. His new priced Catalogue sent to any address on application. H. P. has on Sale all kinds of Turkey and Honey-Comb Sponges.

## Lectures.

## CLINICAL LECTURE ON TWO CONTRASTING CASES OF ACUTE ECZEMA.

By C. HANDFIELD JONES, M.B., Cantab., F.R.S.

PHYSICIAN TO ST. MARY'S HOSPITAL.

M. A. W., æt. 22, female, admitted September 9, 1864. When brought into the hospital this young woman was really in a pitiable plight. She was wrapped up in rags, which were more or less soiled with discharge, and adherent to her skin. No clothes could be put on, so that her only outer covering was a sheet thrown around her. She had been ill four and a-half months; the disorder had come on without any known cause. She was worn, feeble, and emaciated. Almost the whole cutaneous surface was red, more or less excoriated, and covered with thin lamellar crusts. The ears and scalp were much affected, in some spots presenting the characters of impetigo. The lining membrane of the eye-lids was very red. The eruption first appeared on the abdomen and breasts, and afterwards extended all over the trunk and limbs. The pulse was feeble, not excited. The urine was pale-coloured, neutral, not albuminous. She was ordered *Lig. Potas. Arsenit. ℥ v. + Tr. Cinch. ʒi + Tr. opii ℥ v. + Aq. ʒi. ter die*, and a lotion containing *Lig. Plumbi Diacet.* On the 19th ʒol. *Morrh. ʒi ter die* was added. The dose of Fowler's solution was gradually increased to 7, 10, 12, and 15 minims, and, for some time, a drachm of Rochelle salt was given in water, with *Tr. Calumba. ℥ x. bis die.* The inflamed skin, after being well bathed with the lead lotion, was freely anointed with olive oil, which prevented the linen from sticking to the surface. The eruption was most severe on the back at its upper part, and on the backs of the hands, which were cracked, and scabbed, and sore; and benefit was obtained by washing these parts over with solution of nitrate of silver, gr. x. ad. ʒi. By November 26th, she might be called well. There was scarce any trace of the eruption remaining, but the conjunctivæ were still congested. The pulse was soft, open, 126; she was sitting up. The arsenic was now exchanged for Quin. *Disulph. gr. iij. ter die.* A few gelatine baths were administered, and she went out with an almost perfectly natural integument, December 17th. She remained in very good health until about the beginning of June, in the following year, when a relapse occurred, and she was admitted into the hospital again, July 1st, with severe and extensive eczema affecting the chest, abdomen, back and nates. These parts were covered with thick crusts, beneath which the skin was raw and very red. Pulse 108, full; tongue clean and moist. She looked in much better condition than she had been in on the former occasion. The treatment employed was essentially similar until August 19, when the note is that the eczema is just well, but her eyes are much affected; caustic had been applied to one (not by me) and had caused much irritation. A day or two after this the surface of the chest and arms presented a copious eruption of red papules, coalescing into a continuous red surface about the axillæ. She did not feel notably ill. I directed the arsenic to be omitted, and Magnes. *Sulph. gr. xv. + Quin. Disulph. gr. i. + Acid s. dil. ℥ x. + Aq. ʒi.*, to be taken *ter die.* By September 6th the eruption had declined much, but there still remained a great deal of red spotting and patching of the chest and arms, and the eyes were very red; pulse of fair force. The arsenic was renewed in ℥ x. doses, and raised on 19th to ℥ xv., and on 30th, to ℥ xviiij *ter die.*

October 4th. She is reported as doing well, the ears, which had been swollen, red, excoriated, and discharging, were much better. A gelatine bath was ordered, *o. n.* By October 14th, she was able to leave the hospital. It is worth mentioning that an ointment composed of Zinc Oxide, Plumbi Carb., and Hydrarg. Nitrico-oxydi, the latter in small proportion, caused great irritation and aggravation of the disorder, but agreed well when the red precipitate was omitted.

There can be no question that the chief curative agent, on both occasions, in the above instance, was arsenic. Yet I do not think that it was so effective in the second as in the first attack. The skin, it is true, got well covered with epidermis, and fairly sound, but it showed, even to near the last of her stay, a notable tendency to get red and and flushed. I am much disposed to connect this with the improved condition of her bodily health on the last occasion. She was then much less worn and emaciated, her vessels were better filled with blood, her heart's action stronger, and her general nutrition in a better condition. Her cutaneous nerves and arteries, however, were defective in tonicity, and easily allowed the tissue to become hyperæmic. In such conditions it is often very difficult to limit the action of the remedy to the parts which we wish to affect. The weak nerves and vessels need a tonic, and perhaps a powerful one, but the cells and fibres among which they pass are too irritable to tolerate it, and by their disordered nutrition aggravate the very hyperæmia which might have been jugged could the action of the remedies have been directed as we wished. That arsenic does act on the proper tissue of certain localities, as the mucous membranes of the stomach and large intestine, cannot be doubted by any one who has witnessed its toxic effects. I once poisoned a dog by inserting some arsenic into a wound at the back of his neck. On dissection the splenic region of the stomach was found intensely inflamed, the pyloric but slightly, the large intestine very much, but the small was nearly exempt. In the stomach, it was very remarkable how much more intense the inflammation was at the upper parts and free margins of the rugæ than at the lower. The exemption of some parts, and the severe affection of others, seems to me necessarily to imply a special action of the poison on the tissue of those parts, distinct from its general influence on vessels and nerves. On these grounds I think it reasonable to believe that arsenic may exert an injurious influence on the tissue of the skin, which may nullify its otherwise beneficial action on the vessels and nerves. Some such view as this is absolutely required to explain the fact that a healthy conjunctiva may be inflamed, and an inflamed one cured (in certain conditions) by the use of this drug in non-homœopathic doses.

H. C., female, æt. 50, married, but has had no children, admitted January 25, 1867. This woman was not placed under my care till March 3. During most of the previous time, viz., twenty-four days, she had been treated with moderate doses of *Liq. pot. arsenitis*; for twelve days she had *Potass. iod. gr. iv. + Dec. cinch. ʒi. t.d.*, and sulphuret of potassium baths. She was stone deaf, so that it was no easy matter to communicate with her. Four years ago she suffered with the same disorder as at present; was then in the Middlesex Hospital. Her left leg was then affected, and so it was this time on admission, but the disorder has since then extended to the right. All last summer she suffered with severe "flushings" over chest and arms, and rigors. Feels very weak; always does even when well; is very subject to hysterical fits. She seems to have been ill, as she is at present, several months (many she says). Complains now of cold shivers at times, and of smarting, shooting, tingling, and burning sensations in the affected parts, and indeed all over her, which have allowed her no rest night nor day for five weeks. The skin of both thighs, and of the legs, and of the lower part of the abdomen, is of a bright deep red, quite excoriated, and discharges copiously, so that the bandages get stiffened. Her appetite is very bad; her stomach turns against food. Her chest is sometimes affected, and she complains of a good deal of cough. *Ungt. Zinci. ʒi. + Plumbi. sub-carb. ʒi. ft. ungt. part. affect. illinend. Mist. potass. citratis. effervesct. ʒiss. + Magnes. sulph. gr. xx. ter die. Extr. Cannab. ind. gr. ½ + morph. muriat. gr. one-fifth, ft. pil. tus. urgente ssd.*

16th. Is improving very much; her thighs are pale and nearly natural, only the skin is scurfy; the left leg is tender and sore about the middle of the front of the tibia,

and the skin is red, and denuded of epidermis, and encrusted with discharge. A small proportion of red precipitate has been added to the ointment, gr. 20 ad ʒiij.

23rd. Is worse last two days; has got a considerable eruption, of papular character, all over both thighs, attended with much sense of heat, pricking, and shooting. Bowels a good deal confined; tongue clean; pulse 108, of good force. Has had O. diet and porter hitherto; omit porter. Pil. hydr. gr. v. h. n.; pt. c. mist. c. magnes. sulph. ʒi. ad ʒiiss.

25th. Was very poorly last night, with pains and hot flushes about her; the pains shoot with shuddering all over her; her arms are so painful at times that she can hardly move them. Bowels well open; appetite bad. The papules have changed into minute vesicles, which, however, are drying up without discharging. Quin. disulph. gr. i. + magnes. sulphat. ʒss. + acidi. s. dil. ℥ x. + spl. æth. chlor. ℥ x. + aq. ʒi. *quater die*. Lotic glycerinii.

April 3rd. The two thighs are now perfectly natural, the excoriated part of the left leg, over the crest of the tibia, is healed, and she feels no pain in it, though the epidermis is still thin, and the skin somewhat congested. There are some groups of discrete red spots (true small *petechiæ*) on the upper and back part of right leg, and some larger ones, more scattered, about the lower and back part of left. Takes food well; has no pain at all. Going out to-morrow.

The appearance of the diseased skin in these two instances was closely similar, it might be said identical. No dermatologist would have hesitated to pronounce them both examples of the same disease and in the same stage. The hyperæmia was somewhat greater in H. C. than in M. A. W., but it was only a difference in degree, and both, I repeat, were typical examples of acute eczema. But were they indeed truly the same disease? I presume that a chemist who had two perfectly clear colourless solutions before him, whose composition was unknown to him, would not consider them identical if they reacted differently with the same test. Some of the ingredients might be the same, but there must be some material difference between the two fluids. So it is, I believe, with cases of eczema like those I have detailed to you, they are apparently similar, but not really and completely so; and, unfortunately, not so in that which is of far most importance—viz., their therapeutic requirements. What was it that made the difference? Shall we assume with the humoralists—first, that eczema depends upon some “*materies morbi*” in the blood, and then that this “*materies*” differs in different cases? This view I believe to be fundamentally erroneous, chiefly for the reason that eczema is often cured by a tonic non-*evacuant* remedy as arsenic without any impairment of, but on the contrary, with great improvement in the general health. A more probable opinion I hold to be that the vital action, or susceptibilities of the human body are different in different individuals, as we know is certainly the case, and that consequently we get great variations not only in the quality of pathological processes, but in the way in which these processes, when established, are affected by remedies. That in our second case the disease was materially increased by the administration of arsenic there can be no doubt, and I am anxious that you should always bear in mind the possibility of this occurrence, and not look on this remedy as one which is in the least a specific for skin diseases. It is, I believe, nothing of the sort, its *modus operandi* is tolerably intelligible, and like all our good remedies, or almost all, it is capable of doing harm as well as good. When I give nitric acid, or *tr. ferri muriatis*, or quinine in an asthenic bronchitis, I have the same fear before my eyes that I have when I give arsenic for the cure of a cutaneous eruption. I fear lest they should chance to act as irritants and not as tonics, or as I have previously put it, that they disturb the nutrition of the tissue instead of toning the vessels and nerves.

This subject of the varying and uncertain quality of diseased conditions whose outward show is almost, or quite

identical, seems to me of so much consequence, and to be so often left out of account that I must try to illustrate it a little more. At p. 82 of Mr. Green's “*Compendium of Disease of the Skin*” you will find the detailed history of a case of severe eczema of the hands occurring in the person of a lady *æt.* 40, of a sanguine bilious temperament. She was very desirous of trying the sulphur fume bath, which is suitable in nearly the same conditions that arsenic is, but it was not deemed judicious to commence it until she had been bled to ten ounces, had twelve leeches applied to each hand, and been well purged. Even with these preparations the fume bath increased the irritation and had to be discontinued, and it was not until she had been bled several times from the arm to sixteen ounces; had more leeches to the hands, and repeated purgation, that the fumigations were well borne and acted beneficially; she was cured in about three months. Here it seems evident that the depletion had no immediately curative effect upon the local disease, but, nevertheless, it was essential, as it modified the vital condition of the affected tissue, and rendered it tolerant of, and amenable to, an application which previously was only injurious. Some five years ago I observed a case of severe and extensive eczema in our wards, which was treated with arsenic and the sulphur vapour bath, and an occasional *v. s.* to six or eight ounces. This patient had been bled three times, and always with benefit. He was not under my care, but very shortly after his daughter was with very much the same disorder; she was, however, a person of weaker frame, liable to semi-syncope attacks, and probably not so well fed as her father, who had full diet in the hospital. I treated her with arsenic and bark without any depletion, and her recovery was almost complete when I last saw her. Is it not reasonable to regard the disorder in these two instances as of different quality, so different that the treatment could not but vary correspondingly? Let me place also before you two instances on a smaller scale, where the action of a simple remedy produced very different effects. The first is the case of woman *æt.* 43, who, at the time of her admission for acute rheumatism, had on the inner and outer side of the left foot and ankle a large patch of erysipelatoid inflammation. The part was wrapped up in a poultice, and in twenty-four hours the hyperæmia had quite disappeared. The acute rheumatism was treated with *pot. iod.*, *pot. bicarb.* and *dec. cinchon.* and presented nothing else unusual in its course. In the second case, a female *æt.* 25, suffering with rheumatism fever and pericarditis, and pleural effusion, had poultices applied to the precordial region and left back. Shortly afterwards a copious dull red spotty eruption came out on the skin so treated and extended to the axilla and neck. It was evidently of eczematoïd character, and exhibited speedily some vesicles full of sero-purulent fluid. There can be no question that the poultice, that is moist warmth continuously applied, produced very opposite effects in these two instances—in the one removing hyperæmia; in the other producing not only it, but the further result of inflammatory effusion. Must not the vital condition of the skin have been materially different in these two persons, and supposing them to have been attacked with eczema as the primary disorder, is it not most probable that it would be necessary to adopt different treatment?

In conclusion, take the following as a fair inference from the foregoing experience. Do not suppose that diseases are uniform entities ticketed (so to speak) in books with their appropriate remedies, and that all you have to do is to find out the name in order to have the treatment. This may do for counter practice, and sundry and various “*pathies*,” but not for rational medicine.

#### OSMOTIC PROCESS FOR SEPARATING SUGAR.—

In France, sugar has been lately separated from beet molasses by applying the osmose principle. The membrane used is paper-parchment. Water is passed upwards and molasses downwards on the opposite side of the membrane.

CLINICAL LECTURES  
DELIVERED IN  
STEEVENS' HOSPITAL,  
TOGETHER WITH  
OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

REFLECTIONS ON THE CAUSES OF DROPSY.

(Continued from p. 481.)

Now, the essential characteristic of all fevers, whether idiopathic or symptomatic, is a wasting and softening of the tissues. Febrile movements in the system present themselves under an infinite variety of forms, yet there is one point at which they all meet, viz., a wasting and softening of the tissues, whether it be the short-lived paroxysm of intermittent fever, or the persistent hectic fever, or the irritative or continued or remittent fever, or any of the intervening varieties,—it is a fact, that so long as the febrile movement is in operation, there is and must be a wasting and softening of the tissues, rapid in some cases, exceedingly gradual and slow in other cases, hence the condition is produced which may issue in atonic dropsy.

It should be kept in mind also, that so long as fever is operative upon the system, the digestive function is enfeebled,—the nutriment received into the stomach lowered in quantity as well as in quality, often to an extreme degree; frequently the food is liquid, watery, and almost purely farinaceous. From this cause, as well as from morbid action, the function of sanguification is altered, and the blood degenerated, and rendered less capable of stimulating the vascular system to the healthy discharge of its duties. This is precisely the condition of the liquids and solids which predisposes to dropsical effusions of the atonic character; or, in few words, the blood is degenerated, the tonic and contractile force of the vascular tissue depressed, and hence, spontaneously (or, as happened in the case above narrated, after slight and premature exertion whilst in a state of extreme debility), congestion takes place, and a thin serosity is extravasated. So long as the cause remains, this persists and increases; the cause removed, it is wonderful with what celerity the absorbents—those ever-busy little creatures, always ready to undertake any new and extraneous office, ever prepared for all emergencies, sometimes for more than is required of them—set themselves to work, and cause to be carried off, through some one or other of the excretories, the superabundant fluid: the thinner the fluid, the more readily is their task performed. In the case narrated, when the tone of the system was elevated, it was not a little remarkable how very rapidly the extravasated fluid was absorbed. I have seen such an amount of fluid within a few hours absorbed and carried off through the kidneys as would exceed credibility.

As a proof of the share which impaired tonic force has in predisposing to hydropic effusions, I may mention the case of a patient admitted some years ago into Steevens' Hospital. He had been not long before discharged as convalescent from a fever hospital. His appearance was that of extreme wretchedness and destitution; he was paralyzed on the right side; the whole of the right side was one pellucid mass of dropsical effusion, pitting on the slightest touch. Along the left side there was not a trace of effusion, not even at the ankle or instep. When undressed, he presented as strange an appearance as ever met my eye.

I saw this day a gentleman, aged 65, whom I had seen several times within the last three months. When I first saw him both limbs were cedematous. There was effusion

also into the infra-cutaneous serous membrane of the penis, scrotum, and abdomen,—the cause, obstructive disease of the heart. The right limb was swollen far more than the left, even at one time to double its size. He had, for years antecedently, chronic disease of the hip-joint, which issued in shortening and wasting of the limb. The heart's action has been rendered more tranquil; the effusion has been absorbed; a slight œdema at the ankle and instep of the wasted limb still remains.

I have seen cases of inveterate disease of the sciatic nerve in which atrophy of the affected limb was followed by œdema. Thus it happens that atonicity of the vascular tissue is one of the predisposing causes of atonic dropsy.\*

The atonic dropsy, of which we now speak, is most apt to arise in those forms of wasting disease which involve—in impaired function—the digestive apparatus. For example, there may be, and often is, chronic and ultimately fatal disease of the brain with paralysis, and all the while the patient eats largely and fattens. Many other instances might be adduced of both acute and chronic disease, not in the least involving the conditions necessary to the production of atonic dropsy.

The following case exhibits, distinctly featured, the variety of dropsy now under consideration. It is the only example of the disease described by me some years ago in this Journal, under the title of "Regurgitation without Nausea," that I have met with, of which dropsical effusion was a symptom.

An unmarried woman, twenty-three years of age, rather tall, with a light olive tint of skin, and dark hair, was three years ago affected with small strumous abscesses upon the wrist of the left hand; slow and tedious was the course they ran; they suppurated and cicatrized, leaving the characteristic marks. Scarcely had they cicatrized when she began, without the slightest nausea or sickness, to regurgitate her food. A very large proportion (her friends intimated all) of the food received at each meal was, portion after portion, without the least feeling of distress, returned. The daily regurgitation of a large portion of every meal had, for upwards of two years, persisted. Animal food, till within the last few weeks, had been loathed. All the usual garden vegetables were instantly regurgitated. Potato and egg remained not a moment. Except cream in very small quantity, no oleaginous article of diet was retained in the stomach. Bread in various forms, biscuits, and pea and bean flour, well cooked, seemed to suit the stomach better than other substantial articles of food. Broths and jellies were particularly disliked. For weeks the patient was almost wholly sustained by asses' milk: this too was ultimately loathed. No matter what the food, the daily regurgitation went on, much more of some than of other dietetic substances being ejected.

This case was not an exception to the general rule observable in this disease, namely, that whilst the food is regurgitated, medicine is retained.

Gradually, almost imperceptibly, she became emaciated, until at length she was reduced to a state of attenuation, as low as I have ever in the final stage of phthisis witnessed. The pulse a thread; the heart's sounds, emaciated as she was, barely audible; muscular power prostrated; mental energies reduced to nearly a state of apathy; deficiency of animal heat; chilliness and icy coldness of extremities. The bowels, except stimulated by aloes, never evacuated; the catamenia entirely suppressed; the renal excretion diminished in quantity, in quality normal. Such was the state of the patient when a slight œdema at the ankles was first perceived; rapid was its upward extension till it reached the knees and hips; greatly were the limbs swollen; extravasation, undiscernible by the eye, was diffused over the trunk, and was detected by the sustained pressure of the stethoscope leaving a circular pitting or in-

\* Sometimes the atrophy of a limb is caused principally by interruption to habitual muscular action. There are cases of paralysis in which the pulse of the paralyzed limb is weaker than at the sound side. Such are examples of lowered vascular force and contractility.

dentation. The transparency as well as softness of the œdema were not a little remarkable. Chalybeates were now given in very full doses, and did not fail to produce effects the most salutary. The advancing progress of exudation was arrested; nutriment was more abundantly received and digested; the œdema gradually abated, and after a time wholly disappeared. This patient was afterwards attacked with influenza, fever, and bronchitis. For several days she was compelled to remain in bed; she was again greatly emaciated and debilitated. When she recovered, so far as no longer to be obliged to remain in the recumbent position, the dropsy partially reappeared; again it yielded to the same tonic and ferruginous treatment. Her recovery had now so much progressed that my apprehensions as to the existence of obscure glandular disease, involving, perhaps, the thoracic duct, were proved to be groundless.

In this example of general anasarca there were present all the causes which predispose to white blood effusions of the greatest tenuity; prolonged derangement of the digestive functions, wasting of the tissues, degeneration, and, as happened in this instance, diminution of the quantity of the circulating fluids, and atony of the vascular system. This was rendered manifest by the persistent smallness and weakness of the pulse, and by the continued feeble action of the heart. The result was dropsical effusion, and that too, as I believe, without any visceral disorganization. This case was not one of chlorosis; it was destitute of the essential features of this affection—not many cases of true chlorosis terminate in atonic dropsy. I have, however, seen cases of chlorosis which, in defiance of all treatment, have terminated in dropsy and death. But, in general, few diseases more unfailingly submit to well-directed treatment than chlorosis.

Of the following case, the notes of which I have long preserved, elucidative of the form of dropsy now under deliberation, I shall give a brief and much condensed statement:—

A young and beautiful woman, in the middle rank of life, highly but self-educated, of great mental endowment, of admirable taste, and strong sensibility and attachment, was, unconsciously, the one by whose hand a poisonous dose was administered to her sole surviving parent, to whom she was attached with all the fervour and devotedness of a daughter's love. The phial contained an ounce and a half of laudanum: it was given in mistake for a senna draught. When presented to him by his daughter, he tasted it, and said he did not like it, and would not take it. He had not been in good health. It was with much entreaty he was ever prevailed upon to take the medicine prescribed. She urged him, in terms the most affectionate and persuasive, to take his draught. He replied, "Dearest, you know I never can refuse you anything," and swallowed it. Three hours passed away before she was aware of her terrible mistake. She was aroused to it by the perception of the state of stupor into which her father had fallen, when it flashed across her mind. She found the senna draught, which she intended to have given, untouched; she also found the word *poison* printed in large letters on the empty phial. The shock to her mind was terrific; she became like one insane. All possible means were employed to save the life of the poisoned man, but they were employed too late. He died profoundly comatose at the end of a few hours. From the moment of his last expiration a change came over her; she was lost to all knowledge or notice of persons and occurrences around; she lay like a statue, pale and motionless; food she never took, except when it was placed upon her tongue. The only sound which escaped her lips was a faint "yes" or "no." When asked what ailed her, she would place her hand upon her heart. Her extremities were cold; she sighed and shivered frequently, and dozed brokenly and protractedly. To her the world, and all things in it, were a blank. Tonics and stimulants were administered; air and scene were changed; kind and compassionate relations and friends tried, and tried in

vain, to rouse and to console; she pined away, and nought but a breathing skeleton remained. She lingered on, with very little variety or alteration of symptom, for ten months. Before her dissolution she became œdematous. The swelling, soft and transparent, was first perceived in the lower extremities; it gradually progressed upwards; it became apparent on the backs of the hands, along the arms, and ultimately it was universal.

All the viscera, spinal, cerebral, thoracic, and abdominal, were patiently and minutely examined: no trace of organic change of structure could be detected. There was a copious effusion of thin, transparent serum into every cavity, into every serous tissue. The pericardium was separated from the heart by an abundant effusion; the large amount of the dropsical effusion contrasted strangely with the extreme attenuation. In this case, to repress the increasing dropsy, acupuncture had been several times practised, always with relieving effect; even with this deduction the viscera appeared, as it were, bathed in water.

This poor patient, beaten down in mind and body, breathed her last without a moan or a painful struggle. The mental shock had paralyzed the vital actions, an evidence that in real life events do occur which transcend even the highest flights of fiction.

An almost total suspension of nutrition, sanguification, and vascular energy, characterized this case. The result was universal dropsy, consisting in the thinnest serosity.

I shall transfer to these pages cases formally published in my essay on chlorosis—cases in which life appeared to have been saved by acupuncture. They are precisely the kind of cases to which acupuncture can most safely and most curatively be applied.

Acupuncture removed the tension or vascular congestion which impeded the function of the absorbents: after its relieving action there was a copious flow of urine, a rapid subsidence of the dropsy, just as happens in that variety of dropsy (hereafter to be described) which has been termed obstructive dropsy.

In obstructive cardiac disease, the dropsy often increases despite the most powerful diuretic and cathartic medicines: one small bleeding from the arm suffices to alter the whole condition of the vascular system. The congestive tension of the vessels is removed; immediately the absorbents work, and the diuresis becomes profuse. The bleeding is adopted not at all with the view of subduing inflammatory action, but solely with the intention of unloading the congestion of the vessels, and giving full scope to the action of the absorbents.

For this valuable practical rule I am indebted to my late friend, colleague, and relative, Dr. John Crampton, who has, by lectures, and publications, by useful suggestions in the treatment of disease, done very much to enhance the value and to enlarge the domain of clinical instruction and science in this metropolis. I shall have occasion again to revert to Dr. Crampton's published recommendation of bleeding in dropsy, and when and where it is applicable. The following cases are well calculated to illustrate the subject of the present investigation:—

"A married lady, aged 19, had been for several months labouring under gradually increasing chlorosis. Previously to her marriage she had looked pale and delicate, and had lost much of her accustomed health, strength, and spirits. Marriage, it had been expected, would have had a salutary effect: and for a short time, whilst travelling, her health appeared to improve. She again, however, became languid, depressed, and pallid, and at length universally anasarcaous. In this state I first saw her. She was confined to bed; her debility so great that it was with difficulty she could be moved: and her whole person was enormously distended. Her face was œdematous, but less so than every other part of her body; a copious serous effusion had taken place universally into the cells of the subcutaneous serous tissue. Her pulse was incalculably rapid, and so feeble that it was with difficulty it could be felt at the wrist. The heart's impulses were languid in

the extreme, but unaccompanied by any abnormal sound. The respiration was permanently and greatly accelerated. The alvine excretions were liquid and of light yellow colour; she was so weak and helpless that she could not be placed on the bed-pan. The urine was light-coloured, not copious, of low specific gravity, but without a trace of albumen. A variety of treatment, both tonic and diuretic, had been in vain employed, and all hope of recovery abandoned; and yet there was no evidence of organic disease; the sole change which had taken place was in the blood itself. From the appearance of the skin, and from the slightness of the pressure necessary to displace the fluid, it was evident that the effusion was of the thinnest nature. Under these circumstances I thought this an unusually favourable case for acupuncture. The operation was immediately performed; a great number of punctures were made, from which thin serum flowed copiously, and much care was taken to keep the patient dry and warm. Common salt was dissolved in water, to which the muriated tincture of iron was added; and of this as much was given, at regular intervals, as the stomach could easily endure; together with farinaceous nutriment and wine. On the next day the patient's condition was in every respect an improved one; the anasarca was diminished, the pulse more distinct and less frequent, the respiration less hurried, and the urine much increased in quantity. On the second day many additional punctures were made, and on the third day they were again repeated. After this day the greatly increased flow of urine, and the marked diminution of every urgent symptom, rendered it unnecessary to reiterate the operation. She gradually—I may truly say rapidly—recovered; her restoration was perfect; she became vigorous and even florid; she has borne several children; and many years have since elapsed, leaving her in the enjoyment of uninterrupted health.

(To be continued.)

## DR. RICHARDSON'S LECTURE

ON THE

### INFLUENCE OF EXTREME COLD ON THE NERVOUS FUNCTIONS.

#### PART II.—PRACTICAL.

On the 4th instant, Dr. Richardson delivered the second part of his Lecture on Cold, being the last of his series of Lectures on Experimental and Practical Medicine, prior to the recess, lasting until October. We have already furnished our readers with a full account of the first portion, and are so confident in the interest that it excites, that even in the present crowded state of our columns, we are glad to continue the subject. It is a matter of congratulation that at length Dr. Richardson should have found a sphere for his work so peculiarly adapted to his talents, and should have had the courage boldly to commence this series of demonstrations. From the increasingly influential character of the audiences, it is clear that the effort is appreciated, and we sincerely trust that after the recess the lectures may have a still greater success.

After a preliminary recapitulation of the main points demonstrated in the last lecture, and which we fully reported in our number for 15th May, Dr. Richardson repeated the experiment of freezing a frog. Next, as rather a coarse illustration of the fact that extreme cold may change the molecular condition of even inanimate substances, he directed the ether spray on the box containing the mainspring in his watch, thereby arresting its motion. He then went on to state his opinion that the phenomena observed on freezing the animal tissues, depend essentially on a change in the condition of the water of the body. By the cold the water is transferred from a liquid to a solid state. Nerve tissue contains eighty-five per cent. of water. Make this water solid, and we get all the phenomena of negation demonstrated—a sort of temporary

death. These phenomena may be produced also by other means. Heat is capable of bringing about a similar state. Abstract the water, dessicate the tissue by any means, and the result is the same. In illustration of this, a solution of brain matter was placed on a piece of glass, and on the spray being played upon the opposite side of the glass, a visible change was brought about. This was owing to the solidification of the water, and the separation of the albumen. The same appearance was produced by dropping on the matter some absolute alcohol. This result was brought about by the great affinity of the alcohol for water, depriving the brain matter of this substance. Heat was next applied by means of a spirit lamp. This agency brings into play similar sets of phenomena.

These three experiments were all shown by the lecturer, who remarked that thus, by congelation on the one side, and coagulation on the other, we get exactly the same phenomena, and then went on to refer to some things which are more subtle in their action than these. But these more subtle agents are no less definite in their effects.

Take, for instance, shock, which suddenly produces the phenomena of negation, seen in freezing the nervous centres. Again, a blood change is equally subtle in its operation, and the same may be said of pressure on the brain, which exerts a very definite influence. The lecturer conjectured that probably the effects of certain sounds and odours on the brain, might be explained in a similar manner, and so of certain sights which are known to produce the same phenomena. Moreover, loss of blood leads to the same change—the abstraction of the watery part of the nerve tissue. This leads to a conjecture that some of the phenomena of the collapse stage of cholera may depend on the abstraction of water, and the crystallization of the nerve matter in the body.

One of the most striking things in all these experiments on animals is the local independency of the several portions of the nervous system. Every part seems to have its own centre, so we can isolate many parts of the cerebrum. We may act on one hemisphere or both, or on the cerebellum, or on the medulla, or spinal cord. But we do not thereby necessarily interfere with the functions of the other parts of the nervous system. This fact explains many things in connection with, or in elucidation of, brain disease. There is, nevertheless, to be noticed a kind of balance of one part by another. In reference to this, it is clear that one hemisphere balances another. The corpora striata balance, and are balanced by, the cerebellum. The medulla is thus in the same relation with some obscure point not yet fully made out. One part of the medulla balances a part of the spinal cord connected with respiration. The medulla presides over the muscles used in inspiration; the part of the cord balanced by it presides over those of expiration. If we freeze the medulla we stop the breathing, but we stop it by arresting the inspiration. In the opposite case, that of freezing the segment of the cord balanced by the medulla, we stop the breathing by arresting the expiratory act. Thus, in the nervous functions there is a balance of opposite powers, just as in the muscular system there is a balance of flexors and extensors. This is of considerable import in a pathological point of view. In diseases in which there is a tendency to fall forwards for instance, this propensity may indicate disease of the corpora striata; but it is to be remembered that the disease may be negative while the symptoms only show overaction of the balancing part. The disease may be the result of negation of the function of the corpora striata, while the phenomena of the disease, the symptoms, are those of excessive or unregulated action of the cerebellum. Psychologically, these experiments are also interesting. This is, perhaps, illustrated in the act of going to sleep in the upright position. Sleep seems to begin in the visual organs. As the anterior part of the brain first loses its power, we see the tendency to nod—to fall forwards—caused by that part becoming inactive, while the posterior parts retain their function of propelling. The same may perhaps be said of the shock which sometimes results from looking down

great heights. This shock paralyses the anterior or thinking part, and the cerebellum retains its power, and so gives an impulse forward. This question might be put to the test by sportsmen. A bird shot flying will fall at once, rolling over and over *forwards*, while another turns over many times backwards, in its descent. Dr. Richardson believes that in one case the bird will invariably be found shot through the cerebrum, and in the other through the cerebellum, and he suggested that this fact should be noticed by such of his hearers as had the opportunity of joining in the sports of the field.

In diseases, exactly the same reasoning applied. An instance of suicide by hanging was mentioned. The man, however, had on, at the time of his attempt, a soldier's stock, which, by its compression on the jugulars, caused extreme pressure on the brain, the ventricles after death being found full of effused liquid. He was cut down alive, and immediately ran forwards several yards to a wall; afterwards he had the same symptoms. A man at Newcastle-under-Lyne lost a portion of the bone of the skull, and on pressure on the brain, it was noticed that he pitched *forwards*. It was also observed that in certain states of the weather a similar tendency was evinced, probably when the atmospheric pressure was increased.

In therapeutics, the experiments may be of great value. First of all, they may indicate the mode of action of alcohol. This fluid abstracts water from all the tissues, and most of all from the brain. But there is along with this a liberation of heat, and then a loss of heat, as the alcohol passes away with the water it has abstracted. Thus we have direct loss of water from the brain-tissue, and loss of heat from the whole body.

By a subtler action, ether and chloroform modify the relations of water and albumen. It was thought, years ago, that chloroform suspended oxidation. The idea arose with Snow, but it was not clearly shown to be fact. Some have thought that the chloroform was absorbed and picked up caloric in the system, and by expansion in the closed cavity of the skull, caused pressure on the brain. This idea was suggested by finding that if the skull be opened while an animal is under the influence of the drug, the brain does protrude. But it appears that some more direct change takes place. Dr. Richardson had placed animals in a rarified atmosphere, and found the effects of chloroform precisely the same.

The effect of nitrite of amyle, more subtle and more remarkable still, was next adduced in support of this view. Then was adduced amylie alcohol. This suspends all nerve function, but the animal, though apparently dead, will afterwards recover. A guinea-pig, to which this substance had been given, was then passed round, and appeared quite lifeless. The lecturer stated that it would recover the next day. On recovery from this poison, symptoms like strychnine poisoning are observed. It is a spinal poison.

*Antiphlogistics.*—The mode in which these may act was next referred to. The familiar experiment of the loss of heat on a solution of salt in water, was shown by the thermometer. Then a frog was injected with a solution of chloride of ammonium. This operation produced artificial cataract. The same effect was next produced on another frog by freezing the eye-ball with the ether spray. In each case recovery took place.

The question was now propounded, can cold be applied for the cure of inflammatory symptoms? The spray has been used to subdue acute mania. Cold below zero, for half an hour at a time, to the anterior part of the skull, has been found quite safe. It has been followed by quiet sleep, and by no extreme reaction. In chorea the same agent has been used.

In recovery from rheumatic affections, in which there is excessive vascularity of the membranes of the cord, it has been used in France, and Dr. Richardson looked upon it as likely to cure.

In ganglion, formed on a nerve, it has been successfully employed to stop pain and motion. This led Dr. Richardson

to try it in tetanic action. To show how far he had pursued this, he injected a frog with 1-45th part of a grain of strychnine, and placed it under a bell glass on the table. For two or three minutes it tried to escape, and seemed lively enough. Then tetanic rigidity came on. When the effect of the poison had become so fully developed that the least touch caused violent convulsions, the cerebrum-spinal cord were frozen by the ether spray, and the effect of the strychnine was completely subdued. A frog does not eliminate rapidly, but possibly an animal with more effective secreting power might be kept frozen until the poison has passed away.

Could we then in tetanus keep a patient frozen until the tetanic poison could all be eliminated? If indeed that disease depend on a poison at all, and may not rather consist in some molecular change, such as may be caused by a shock or a blow:—if we had the hope, there is a great practical difficulty. Over the spinal cord there is so thick a layer of non-conducting tissue that no effect can be produced. In experiments with a delicate thermometer inserted in a portion of the spine, the spray being directed on the outside of the muscles, Dr. Richardson has not been able to make a difference of one degree. Though he would not assert that in the living body, some effect might not be *indirectly* produced through the skin, or its vascular and nervous system.

## Original Communications.

### EPILEPSY:

CASE OF SYPHILITIC ORIGIN: SOME PATHOLOGICAL AND THERAPEUTIC REMARKS: BROMIDE OF POTASSIUM, AND BICHLORIDE OF MERCURY.

By P. C. LITTLE, F.R.C.S.I., Etc.

THE subject of epilepsy possesses, unfortunately, an abiding interest, whether we view it as regards the patient, his home circle, or our Profession. This treacherous malady, too often, alas! prematurely terminates the life of its victim by fire, water, or a sudden extinction of all nervous influence, notwithstanding, perhaps, years of anxiety, watchfulness, and tender care on the part of his friends. In cases of this kind, it is the aim of the healing art, not merely to alleviate human suffering, but to try to discover and remove, if possible, the causes of it. To ascertain these in many instances is impossible, as they are not always intelligible to the senses, nor to reason. This admission in nowise detracts from the inestimable labours of Sir Charles Bell, Marshall Hall, Claud Bernard, Flourens, Brown-Séquard, and others, who have recently enriched our knowledge of diseases of this nature, and have thus laid the foundation of a more rational and effectual line of treatment. With the hope of contributing somewhat towards the same end, I beg to place before your readers the following case of syphilitic origin lately under my care:—

Jan. 23rd, I visited J. T., aged 23, a muscular, short-set gentleman, of good constitution, regular habits, sedentary occupation, quiet disposition, clear and refined mind, who, on yesterday, after breakfast, fell in a fit in the street. I was informed that during the paroxysm, which lasted for about a quarter of an hour, he was insensible; the muscles of his face and upper extremities were violently convulsed; his features were livid and swollen; mouth foaming. On recovering consciousness, he had no recollection of what had happened, and only complained of great weariness, headache, and confusion of mind. A similar attack (the first he had ever had), occurred about six weeks ago, during the night, and was noticed by his brother, who slept in the same apartment with him.

As far as I could learn, the patient was free from any hereditary disease. About four years ago, however, he placed himself under my care, for a large suppurating bubo

in the right groin, and an indolent syphilitic ulcer on the glans penis. Under a gentle mercurial course, he soon regained health and strength, which he possessed until last year, when his hair began to fall out, and he became generally debilitated. For about four months previous to the first fit, he felt very weak and low spirited; suffered "fearful pain in the head," and vertigo, which have been more or less persistent.

He appears to have lost much flesh; is uneasy and anxious in manner; has deep congestion, and frequent flushing of the face and neck; evident pulsation of the carotid and temporal arteries; countenance listless and stupid; eyes—staring and pearly, conjunctivæ injected, pupils slightly dilated, but indifferent to alternations of light; skin cool and perspiring; pulse 88, small, soft, and nervous; tongue brown in the centre; appetite insatiable; bowels pretty regular.

He complains particularly, of an uncomfortable feeling of restlessness day and night; throbbing headache; slight cough; occasional tinnitus aurium; loss of memory,—forgetting that he has taken his full meal, he sits down to eat another; tenesmus, and bloody stools.

On examining him, I observed some specks of a papillar eruption upon the forehead. I could discover no tumors about the nervous centres, or peripheries; no nodes. Pressure upon the epigastrium, and along the colon, but especially over its sigmoid flexure, produced much pain. The abdomen was tympanitic, and unusually sensitive. The roof and posterior wall of the pharynx were intensely red, and studded over with deep, roundish, unhealthy-looking ulcers, their edges sharp, and fringed with grey shreds of the broken down tissues. This condition was, I conceived, the exciting cause of the patient's misery, and to remedy it, I directed my treatment.

I began by sponging the ulcers and the pharynx generally with a strong solution of nit. arg. (ʒj. ad ʒj.), a course which I repeated every third day; ordered a mustard foot-bath, and brisk mercurial purgative, at bed time; rest of mind and body; no strong drink; slop diet; chicken broth, and milk plentifully.

Next morning he said that he felt something better; he slept pretty well; the bowels had been slightly moved, with much distress and loss of blood.

I prescribed, to be taken three times a day, ten grains of bromide of potassium, with a drachm of fluid extract of sarsaparilla in water; a blister to the back of the head and nape of the neck; the mustard foot-bath every night; the bowels to be regulated by the occasional use of rhubarb and blue pill, at bed time, and a saline aperient the following morning.

At the end of a week the nervous symptoms were mitigated, although the ulcers in the pharynx were much the same; the abdominal tenderness more distressing, and blood still passed at stool. I continued the cauterisation of the throat; advised sinapisms to the stomach and bowels, a flannel binder at other times; the occipital blister to be kept open; and twenty grains of the bromide of potassium, three times a day, with the sarsaparilla. Having persevered with this treatment for more than a week, and finding no very marked improvement, I decided upon placing my patient upon a short alterative course of mercury, one-twelfth of a grain of which I administered in an ounce of the sarsaparilla three times a day. In less than a week the gums became spongy; the throat perfectly well; and, in another week every uncomfortable symptom disappeared. For about a month afterwards, I continued the mineral, watching carefully its effects. The patient has enjoyed excellent health ever since.

This case is interesting in many respects. It exemplifies an appalling disease, which is still obscure in its pathology, distinguishable by no regular symptoms, and frequently defiant of all treatment. Pathologists have failed to discover any constant morbid conditions associated with epilepsy; and, in many cases, no alterations whatever are noticeable, which seems incompatible with the present general opinion, that the disease originates from abnormal changes at ner-

vous centres. The most valuable recent addition to our pathological knowledge of epilepsy, seems to have been made by Van der Kolk, who, by pursuing the inquiries of Georget, Prochaska, Hall, Todd, and like observers, has arrived at the conclusion, that "the starting point of the various convulsive movements in epilepsy, must be sought in the medulla oblongata," which post-mortem investigations have shown to be the more generally affected centre of the cerebro-spinal axis.

The admirable experiments of Brown-Séguard have tended to confirm this opinion, and to reveal more clearly the features of this disease, which is characterised by increased reflex motor sensibility, with more or less of loss of consciousness, and of control of reflex action. Dr. Todd gives loss of consciousness as pathognomonic of the disease; but, as that condition is common to many other affections, it cannot be considered as distinctive of this. Besides, in a fit, sensibility may not be entirely suspended, though all other epileptic phenomena exist. Such a case, I have at present under my observation. Diminution of consciousness seems, therefore, to be a symptom, the degree of which is measured by the contraction of the cerebral capillaries. In other words, the medulla oblongata is the centre of reflex movement, the impulse from which is communicated, on the one side to the hemispheres of the brain, inducing impairment of the mental faculties, and on the other to the muscles of the extremities, giving rise to convulsions. The character of the convulsive phenomena has been generally commented upon, and well deserves attention. Dr. Russell Reynolds makes two stages of a fit, the first that of "tonic spasm;" the second, of "clonic," or that called by Dr. Sieveking "the automatic movement." Perhaps Dr. Watson's description of a paroxysm is the most suggestive. He says that, "in most of the fits in which I have happened to see the commencement, the first effect of the spasm has been a twisting of the neck, the chin being raised, and brought round by a succession of jerks to one shoulder."

It has been remarked by Römberg (and I have also observed) that, during a fit, although sensation is suspended, reflex action may be excited by suitable stimuli, such as a dash of cold water in the face, which Dr. Reynolds ably explains by, holding that, "the receptivity of the peripheral expansion of the nerves is not seriously interfered with." Experience has shown that frequent repetitions of those fearful attacks generally end in a permanent impairment, sometimes total loss of the mental faculties, with paralysis more or less complete—the consequences of altered nutrition of cerebro-spinal centres. This constitutes the most deplorable aspect of the disease.

The history and peculiarities of this case facilitated the diagnosis and treatment. Here was epilepsy in a system tainted with syphilitic poison, manifesting itself by chancre and bubo, falling off of the hair, papillar eruption, hæmorrhagic, or ulcerated condition of the bowels, and ulcers in close proximity to the base of the brain—a region intimately connected with the medulla oblongata, the great source of reflex action. The syphilitic origin of the fits, their infrequency, and in particular, the tractable character of the ulcers, were elements of a favourable prognosis. The circumstances of the case indicated the local treatment. The constitutional management was not so evident. From all that has been recently said in favour of bromide of potassium in epilepsy, I determined upon giving it a trial, and from my observations of its effects in this, and in other cases, I can testify to its beneficial effects, which M. Voisin, in the *Bulletin de Therapeutique* of April, thus sums up:—"It is hyposthenic, calming, hypnotic, and slightly alterative; it is of real utility in epilepsy. It does not usually cure absolutely, but it diminishes the disorder in a marked degree; it lessens and even suppresses the nervous erethism of epileptics—the shocks and convulsions which they so frequently endure." In the present case, sufficient time appears to have been given to this remedy, but without the desired relief to the patient. I am of opinion that this salt is not possessed of sufficient alterative properties for

the treatment of epilepsy of venereal origin. Hence, I was obliged to resort to an old and well-tried friend, whose character is unquestionable, and with the happy results I have stated.

The treatment of epilepsy, and of all kindred diseases, advocated by Dr. Chapman, of London, upon the broad principle of regulation of temperature in the vicinity of the cerebro-spinal centres, is really scientific. What can be more reasonable than to try to restore to those centres their normal temperature, which is a condition necessary to their proper functional and organic existence. But is this principle applicable in all cases? It were well if we could say so. Dr. Chapman himself will not assert that epilepsy caused by eccentric irritation, as from worms, a thorn in the foot, or venereal ulcers in the throat, can be eradicated by the application of cold or heat along the cerebro-spinal axis. In epilepsy from spinal irritation, I have no doubt of the benefits of ice along the spine. Some years ago I was consulted by a young man in whom this fearful disease was traceable to spinal irritation, excited by onanism. I admonished him against his injurious habit, and ordered him cold shower baths down the spine, night and morning, which soon reduced the fits from one almost every hour to one or two in the day, and with diminished severity and duration. These good results only continued as long as the treatment was persevered in, and the exciting cause avoided.

Dr. Chapman's principle is surely a rational one for certain cases; but for others, such as the case under discussion, it is unsuitable. It might, perhaps, be more judicious, even at the risk of being considered non-progressists, to select our remedies according to the special circumstances of each case—a practice generally followed by our most distinguished professional brethren from the beginning, and which, in all probability, will continue to the end, unless a more correct and ample knowledge of the nature of this fearful disease, be discovered by the light of pathology and of kindred sciences.

#### CASE OF HYDATID DISEASE OF THE LIVER; SUPPURATION; RECOVERY.

By W. B. PEEBLES, M.B.

Mrs. —, aged 37, previously healthy, after weaning a child towards the close of last year, began to complain of loss of appetite and energy. She had been subjected to a good deal of mental worry and annoyance.

Early in February last I saw her for an inflamed tonsil, which yielded to treatment without suppurating. A fortnight after she was seized with violent symptoms of inflammation of the liver. On the fourth day of the attack I was again asked to see her; she was supported in the upright position on a sofa, as being the easiest one. The countenance was sallow and expressive of great suffering; she coughed incessantly, and complained of intense pain on the top of the right shoulder in the right hypochondrium, epigastrium, and left hypochondrium, passing back to the spine on each side, and shooting upwards to the clavicles, the right especially.

On examination the liver was found to be evenly enlarged, and projecting two inches below the ribs. It was so painful as scarcely to bear a touch, chiefly at the epigastrium and right lobe. The spleen also was enlarged and painful; tongue soft, ash-coloured; pulse 80, weak; bowels loose; urine scanty and high coloured; catamenia present.

It is not necessary to record the details of her tedious and painful illness. From the first, support and opiates were indicated, repeated blisters were applied, and the abdomen kept covered with linseed poultices, as in several places, particularly in the iliac fossæ, the bowels became tender when touched, and had a knotty feel; they also became constipated. Rigors, followed by profuse perspiration each evening, soon set in. The catamenia did not appear at the proper periods, and she complained of a burning pain below

the axilla; irritability of stomach; prostration; headache, and loss of sleep. The urinary secretion, which had varied, became copious. There was delirium occasionally. Large quantities of opium, internally and locally, having failed to induce sleep, the injection of morphia under the skin was found of great use.

The discharge from the bowels, which only took place after medicine or enemata, assumed the appearance of "wet slack" as she termed it. This, when diluted with water, stained paper a red colour, showing it to be altered blood.

She presently began to lose power in the right arm, and to suffer from hysterical symptoms, with palpitations, being impressed with the notion that she had cancer, and that something was pressing against the heart.

On the seventy-third day of her illness, owing to an increase of suffering and great throbbing at the epigastrium, she said to her husband she was sure something was about to happen. Almost immediately after something burst, and she felt fluid pouring into the bowel.

In two hours afterwards purulent matter was discharged per anum, containing a number of small white bodies, like marbles, which were unfortunately thrown out. Some of the black matter also came away, and there was a prolapse of about six inches of bowel, stated to be of a dark purple colour. Great relief was felt with general improvement. In about a week all the old symptoms returned with increased intensity. Rigors, perspirations, palpitations, delirium, and great pain, not at the epigastrium as before, but as high as the centre of the sternum at its right edge. Nothing would stay in the stomach; movement of the bowels—always painful—was followed by fainting. She described the sensation of "another gathering," which, after a fortnight's agony, was discharged into the stomach. A bowlful of offensive matter was vomited. There was immediate relief, but the bowels continued costive and tender everywhere. I feared to give aperient medicine, which was much needed, on account of the state of the parts, and trusted to soothing enemata, to wash away the black matter. From the great soreness when the bowels acted, and from pure blood coming away, it was to be feared that the mucous membrane was becoming abraded. In the discharge one day was found a "firm, white, fleshy substance, egg-shaped, the thickness of three fingers put together, with strings at its ends." I am unfortunately obliged to give the nurse's description of it, but it is not a bad one of a hydatid cyst. There cannot be much doubt that it was one, and that the marble-like bodies discharged previously were of the same nature. It was put aside for me, but a busy person threw it out.

Amendment progressed, the black evacuations after enemata, the constipation, and tender state of the bowels, however, showing that the portal engorgement had not yet subsided.

She is now (May 29) up every day, and doing well.

No cysts came from the second abscess. The tongue was always clean; nothing the colour of bile was to be seen anywhere. The portal system seemed to be completely blocked up. There was no albumen in the urine at any time; after the first week it was profuse, and of low specific gravity. The kidneys, although tender on pressure, escaped, as their veins do not go to the porta; but the spleen suffered.

I think this case worth recording, because—1. Abscess of the liver is not common here; 2. Hydatid disease is still rarer; 3. The symptoms at one time were very like those of cancer. But the malignant expression of countenance and uneven surface of the gland in that affection were wanting.

During the progress of the case, a considerable amount of stimulants was consumed, owing to the weaknesses; but, fearing least alcohol might be adding fuel to the fire, I made several attempts to do with a smaller quantity. This, however, seemed to be imprudent, and if, after rousing the system generally, it increased the pain in the liver, it also, probably, assisted in the adhesive inflammation which has lengthened the patient's life.

MEDICAL SOCIETY  
OF THE  
COLLEGE OF PHYSICIANS OF IRELAND.

The President, Professor STOKES, in the Chair.

(Continued from page 552.)

Dr. HAYDEN said—Mr. President, with your permission I would make a few observations on the important and interesting subject now under discussion. My experience of the disease which has recently appeared in Dublin, and to a limited extent in the provinces, extends only to the two cases which I have laid before the Society, but these cases were of a typical character, and made the subject of careful and anxious study; and to the disease, as observed and reported on in Dublin generally, I have given a good deal of thought. It appears to me that the most important preliminary points to be determined in relation to this novel disease are its general nosological affinities, and its pathology; and in considering it under these two heads we must duly estimate the two prominent groups of symptoms associated with it—namely, the cerebro-spinal and the cutaneous—in relation to the order of their manifestation, their mutual connection, and their relative significance. Only two views can be held of the pathology of the disease—namely, either that it is essentially a form of cerebro-spinal meningitis, a disease with which this country has been long familiar, but modified by the “epidemic constitution” of the time in which we live, and therefore associated with marked prostration, and a peculiar cutaneous eruption, and ecchymosis; or that it is primarily a disease of blood-deterioration, allied to the essential fevers, and implicating secondarily the cerebro-spinal axis. I confess, sir, that I am in favour of the former of these views, notwithstanding that some difficulties arise in the detailed application of it to the disease under consideration. It is noteworthy that in the great majority of cases reported, the attack commenced with symptoms of cerebro-spinal irritation—viz., pain in the head and back, sickness of stomach, morbid sensibility, and tingling sensations of the general cutaneous surface, followed in many instances by retraction of the head, recurvation of the spine, dilatation of the pupils, convulsions, and coma. These are undoubtedly the symptoms of cerebro-spinal meningitis, and, in a very large proportion of the cases reported, including both of those which have come under my own observation, they preceded the cutaneous manifestation by an appreciable interval, varying from a few hours to as many days. Of the two cases which came under my own notice, in one, headache, vomiting, and hyperæsthesia of surface preceded by four days, and contraction of the pupils and intolerance of light, by twenty-four hours, the appearance of eruption on the skin, and in the other, bilious vomiting, and other symptoms of cerebral disturbance occurred about nine hours before the petechial eruption appeared. So far, as to the order of manifestation of the two groups of symptoms. The pathogenesis, or pathological connection between meningeal inflammation and cutaneous eruption and ecchymosis, I will not pretend to explain. I may remark, however, that the recent discoveries of Bernard in regard to the influence of the vaso-motor nervous system upon the capillary circulation, on the one hand, and the intimate connection of that system with the spinal cord, on the other, would seem to warrant the assumption that central irritation of the cord may so modify the tension of the blood-vessels as to favour, if not give rise to, extravasation from the cutaneous capillaries; but this, be it remembered, I offer, not as a solution of a great pathological problem, but as suggestive of a line of argument which may be further profitably developed. Observation and analogy are more to the purpose here. The frequent occurrence of herpes, eczema, and psoriasis, in connection with chorea, is well-known. At the present time I have under my care in hospital a case of right hemiplegia with loss of speech, in which the patient has suffered from two successive crops of an ethymatous erup-

tion on the face and neck, of a most obstinate character commencing on the paralysed side, but subsequently extending to the other. In the great majority of cases in which the advantage of a post-mortem examination has been obtained, evidence of active meningeal inflammation at the base of the brain, and in the spinal canal, has been found; the arachnoid was opaque in many places; serum was effused into the cerebral ventricles, and deposits of lymph and pus were found at the base of the brain, and on the surface of the spinal cord. Now, sir, I would venture to assert, in presence of the many able pathologists assembled here, that such a marked preponderance of active inflammatory lesion of one particular organ, as has been found associated with this disease, is unknown in the pathology of essential fevers. It has been alleged, as favouring the view of the general nature of the disease, that pericarditis and pleuritis have been likewise met with in connection with it, but the proportion in which these complications have occurred (only three cases out of the whole number reported to the Society) is much too small to confer upon them more than an *accidental* value.

Dr. MOORE, Vice-President College of Physicians, said that he had an opportunity of seeing a series of cases with cerebro-spinal symptoms, in Sir P. Dun's Hospital, about eighteen months ago. He had listened attentively to the details of all the cases which had been brought before the Society, and in every instance where a post-mortem examination had been made, evidence of cerebral and cerebro-spinal meningitis had been found, and in two cases which he had the opportunity of seeing, through the kindness of Dr. Gordon, the disorganization might have been termed “excessive,” the whole spinal cord being deluged in pus. The symptoms in so many cases could not be expected to be identical. In one there was violent pain along the spine; in another, paralysis; in a third, vomiting and convulsions, all of which symptoms were admittedly nervous, and such cases are valuable, so far as their details go, in pointing to the same exciting cause; but it is upon the cases where the pathology was obtained that we must chiefly rely, more especially on those of Dr. Haverty, in every one of which evidence of severe nervous lesion was shown, and the same was observable in almost every case which has fallen under Dr. Gordon's notice. As regards the herpetic eruption, which prevails in these cases, Dr. Moore went on to say, that recent experiments have shown that nervous irritation is capable of producing herpetic or some such allied eruption over the periphery, and he had seen this proved in two remarkable instances, when large thoracic aneurisms had given rise to persistent nervous pressure, and to equally persistent herpetic eruptions. As regards the purplish spots, call them “petechiæ,” “maculæ,” or what you will, they must be regarded as hæmorrhagic, and having detailed the close intimacy which is now admitted to exist between the vaso-motor and cerebro-spinal symptoms—so close, that it is difficult to determine where the one stops and the other begins—he concluded that the hæmorrhage was most rationally accounted for by the sudden paralysis of the whole nervous system, more especially the vaso-motor, by which means the blood over the body generally may be said to have been “let loose.” Everything considered, he thought physiology and pathology must lead us to view this disease as essentially of a cerebro-spinal character. Our knowledge of the nature of diseases in the abstract is as yet limited, but with the information we are possessed of, it is as rational to call this prevailing epidemic a “cerebro-spinal meningitis,” as it is to define a disease “pleurisy,” or “pneumonia,” where pathology shows us a pleura coated with lymph, or the lower half of a lung in a state of trepanization.

Dr. T. MORE MADDEN said that he had been requested to say a few words in reference to the observations made by Dr. Smith, on the occurrence of the black death of the fourteenth century in Ireland. In the course of his remarks on a case of malignant purpuric fever, which he read before the Society, Dr. Quinlan had mentioned that he

had been informed that there was reason to doubt if the black death which prevailed in England in 1347 had then visited in Ireland. Dr. Smith, in reply, quoted an authority the name of which he (Dr. M. Madden) did not catch, but which he supposed, must have been Father Clin's Narrative, cited in Harris's "History of Dublin." Now, as he (Dr. More Madden) had mentioned to Dr. Quinlan that no allusion to black death in Ireland in the year 1347-'48 was to be found in the "Annals of Ireland," by the Four Masters, he thought it right to say that last year, when engaged on an essay which he then published on the connection existing between epidemic and epizootic diseases in Ireland in the middle ages—which connection, he might observe, was recently well illustrated by the rinderpest, which preceded and accompanied the epidemic cholera in England last year, he had frequent occasion to consult the "Annals" of the Four Masters, and was particularly struck by finding that these "Annals," which contain special notices of the plagues which visited Ireland, make no reference whatever to the "black death" at the time when it prevailed elsewhere. And, therefore, without having the least doubt of the accuracy of Father Clin's Narrative, he thought it might be of interest, when the history of the disease came under discussion, to mention this omission, as it was certainly curious that a pestilence, so remarkable in its character and so fatal in its results, should have occurred in Ireland in the year 1347 without being observed and chronicled in the cotemporary "Annals" of the Four Masters.

Dr. BANKS said that having seen some cases of the disease under consideration, he should like to state his experience of it shortly. He had seen some cases in which cerebro-spinal symptoms were very well-marked, and in others those symptoms were absent. The disease appeared to him to be altogether a blood disease, and in the observations made by Dr. Gordon on the evening before last he entirely agreed. He had himself reported in the journal some cases of the disease, and there was just one point to which he wished especially to revert, namely, that from the period that this new disease first appeared, he had seen a considerable number of other diseases in which black spots appeared on the surface of the body. He saw lately in consultation with a physician on the other side of town a case of acute rheumatic fever, in which large purpuric spots appeared, in no respect differing from some of the cases of this terrible disease; so much so, that at the moment he first saw them his impression was that the disease was about to assume the character of this most fatal malady. He saw at least six cases within a short period in which these purple spots appeared. It seemed to show, as Dr. Hughes had suggested, that there was some peculiar state of the atmosphere owing to which this asthenic condition of disease was present. He believed the disease they were now considering was in almost all cases cerebro-spinal arachnitis, but there were some cases in which the altered condition of the blood, manifested by the appearance of the spots over the surface, occurred without any sign of cerebro-spinal meningitis being discernable after death. With reference to the name of this disease, he would venture almost to give it a name, but he hesitated because there were so many objections to all the names which had been suggested. He strongly protested against some of them, and more especially against the name "black death." It would be a waste of time to go further into that subject. They all knew the terror it had struck into the public mind when the name first appeared in the newspapers. They all knew that pestilential diseases were frequently fatal to the first persons attacked, but the effect of calling the disease "death" impressed people with the notion that all attacked must die. In almost all such diseases experience showed that the disease decreased in virulence as it wore out, and that the latter cases in every epidemic were not so bad as the earlier ones. He believed this disease was a blood disease, that the greater number of cases were cerebro-spinal arachnitis. He would venture to call it pestilential purpura. It had all the attributes of a pesti-

lential disease, and he thought this name less objectionable than some of the names that had been given to it.

Mr. FLEMING bore testimony to the great interest and importance of the remarks which had been made by the gentlemen who had taken part in the discussion. His observations would be limited to what fell within his special department in the surgical wards of an hospital. He thought, as regarded the nomenclature of the disease, they were all agreed that the fearful appellation "black death" should be given up; and he would suggest that the name which the President had given it would be suitable, as expressing all its essential features, viz.—malignant purpuric fever. The word fever, perhaps, was questionable, for they had heard that the disease had manifested itself without fever. As to its surgical aspect, he would ask those who had witnessed surgical operations and injuries, to recall the supervention of symptoms like these as regards their extreme intensity, and their fatal termination. They were all familiar with them, and especially as regards diseases affecting the periosteum, with eruptions on the skin, and complicated with pericardial effusion.

The PRESIDENT said he would now offer a few remarks on the debate of that night, and on the subject in general. He might observe, in the first place, that his friend Dr. Gordon, in his paper in the *Dublin Quarterly Journal*, had, to a great degree, exhausted the subject, so far as the epidemic of cerebro-spinal arachnitis is concerned. He did not say that he entirely agreed with Dr. Gordon in the general conclusion at which he had arrived as to the pathology of the disease, but, so far as the observation of the local disease went, he thought his paper was an exhaustive one. Now, it appeared that, during the past year at all events, Dublin had been visited by two forms of *essential disease*. The first of them was the affection which they had been discussing that night, and the second was the cholera; and, looking at the invasion of these diseases in the one year, it was very hard to avoid the conclusion that some relation existed between them. The disease which he proposed to call malignant purpuric fever (he was not, however, wedded to that name), seemed to precede the cholera. In some cases it was in its very highest form of development before the cholera broke out. That extraordinary case of Dr. Croly's apprentice, which, as far as he knew, was the first case of the disease, occurred in March, 1866. That young man went to bed feeling a little ill, after sitting in his room during Sunday. His master visited him in the evening, and observed a few petechial spots on the neck. This alarmed him, because so early an appearance of petechia in fever is unusual. He saw him in the morning and the spots were black; they appeared to grow under his very eye. At eleven o'clock the spots were numerous and extremely large, and between eleven and one o'clock the entire right arm and half of the right chest, were as black as the coat of any gentleman in the room; large patches of ecchymosis appeared all over the rest of the body, and the patient was dead at two o'clock. During the pressure of the cholera the disease seemed to be very much less frequent. It seemed to be to a great extent suspended. There were but two cases in the Meath Hospital in the months of October, November, and December, and they were not cases of the very rapid form of the disease. Then when cholera died away this extraordinary disease reappeared, and so far from being confined to Dublin, it appeared in several country districts, and they did not yet know in how many country districts the disease may have appeared. It struck him that this disease had all the characteristics of a most malignant blood-poisoning, and that, though it was in character an essential or so-called zymotic affection, it differed from every form of fever with which they were familiar. Every case had been contributed by independent observers, and the details of the cases presented complications singularly varied, yet there was an amount of generic coincidence among them to justify their classification under one head. How did the disease differ from ordinary maculated fever? It differed from fever in the rapidity with which it ran its course—a course from a few hours to a few

days. The first was a thing unknown in cases of ordinary typhus. It differed also in the eruption—in the character of the eruption, the mode of its appearance, and the duration of the eruption. This disease began in ordinary cases with the eruption, which typhus fever did not; and it differed again in the frequency of one special local symptom—namely, the cerebro-spinal irritation. It might be a question whether these symptoms were the result of reflex action or the result of general inflammation of the structures themselves. The fact was certain that in many cases the membranes of the brain, and at least those of the upper part of the spinal cord had been found inflamed. This was one of the rarest circumstances in typhus fever. Let them consider these points. First, the duration of the disease—the disease had been fatal in less than eight hours—as few as eighteen or twenty hours was not at all infrequent. From five to six days appeared by different cases which had been reported to have been an ordinary proportion, and there were three cases where the disease ran on for several weeks before the patient was convalescent. The eruptions had been very various. In some the spots were elevated. In rapidly fatal cases it had appeared in the form of petechiæ, running rapidly into ecchymosis, the original ailment not being preceded by fever at all. A few hours were sufficient to render a large portion of the body black. Another point of difference between this disease and typhus fever was an important one—the variation in the range of temperature. In one case in the Meath Hospital, the temperature on the third day was below the natural standard—96 7-10ths, and in this case the highest temperature reached was 98 8-10ths. The pulse was only 80. In the second fatal case on the second day, the temperature was 99 6-10ths, and on the third day it rose three degrees. The pulse, on the day preceding death, was 84. The occurrence of cerebro-spinal arachnitis in many of these cases was remarkable. In two cases which he saw, the patients could only lie on the abdomen, and when the trunk of the body was lifted up by main strength, the patient immediately slipped down to the bottom of the bed. There was great variety in these cases of cerebro-spinal arachnitis. One of the first cases of this disease which he saw was marked by some curious symptoms. A boy was taken ill with symptoms like those of cholera; symptoms of collapse set in in four hours; large spots came out on the arms; the head became retracted, so that he could only lie on his belly. He had a low form of fever which left him on the third day, when the spots began to disappear, and the boy had a quiet pulse, but the retraction of the head continued to the most extreme degree, and in this state he remained for seven weeks lying on his belly, eating, drinking, sleeping, and getting fat. At the end of seven weeks the retraction got less and less, and he completely recovered. This was a remarkable fact, showing that they were not to infer from the existence of this special symptom, that there was necessarily cerebro-spinal arachnitis. Another boy had typhus fever, and in recovering from it the retraction of the head took place. He could only convey to them an idea of its extent by saying, that if the boy was raised up in bed, the face was almost horizontal. At this period of extreme retraction, a liniment of iodine was applied to the neck, and the next day the retraction was almost altogether gone. They must not forget that in some cases, neither the local symptoms of cerebro-spinal arachnitis were present, nor were any indications of them found after death. He saw one case where there were no symptoms of cerebro-spinal arachnitis. The patient preserved his senses up to the last. This would tend to show that this lesion was not primary but secondary, and all observation went to establish that it was a secondary and not an essential condition. Let it not be forgotten that in some of the worst cases the symptoms of spinal arachnitis were absent, and if as some supposed the ecchymosis and eruptions were due to disturbance of the nervous centres they should have found in the worst cases of the disease the greatest amount of lesion, but the fact was not so. It might be that there was an epidemic tendency to local disease. Some years since

they had seen a great many cases of abscess of the liver, which was a rare disease. They knew from Dr. Darby, Dr. Law, and Dr. Gordon, that there had been cases of cerebro-spinal disease very frequent, for some years past. But although this disease of cerebro-spinal arachnitis had been naturalized amongst us for years, it was only during the last year that the disease marked by this singular eruption had occurred. Now, there had been an idea abroad of this disease being measles, from the similarity of the eruption in many cases, and it was worthy of remark, that during the time that these cases were most prevalent, measles had been unusually frequent, and unusually fatal. A case had occurred under his observation which showed the difference between this disease and measles. In a family in this town one of the children, a little boy, had well formed and natural measles. A little girl, his sister, sickened, and the parents thought she was getting measles. This was followed by the black eruption which was characteristic of the disease which they were now discussing. After a few days well-marked measles made their appearance, causing a peculiar change in the girl's aspect. All these facts would strongly bear out the view that this disease was a blood-poisoning, and that the cerebro-spinal affection was a secondary disease in this form of fever. Now as to the question of contagion they had had few facts before them until the last day of meeting to lead to the conclusion that this was a contagious disease. Dr. Haverty in his paper, mentioned some facts tending to that conclusion, and they had at present in the Meath Hospital a mother and child labouring under this disease, and who had apparently caught it by contagion. Another child died of this black disease some time ago. Some days afterwards the second child sickened with the same symptoms. The mother slept in the same bed with the child. She sickened the next day, and both mother and child were at present in hospital. These facts were very important with reference to the question of contagion. Although the disease had up to the present proceeded sporadically, there was no reason to say that it might not be of a contagious character. He thought this was a disease of the blood, of an essential nature, and that the secondary and incompetent cerebro-spinal arachnitis was to explain it. The number of cases contributed by members and visitors showed the great value of the Society. It showed that the Society was becoming a great medical observatory, affording men an opportunity of placing upon record cases of a remarkable character, while the facts were fresh in their memory (applause).

The meeting then separated.

## POOR-LAW INTELLIGENCE.

### LONGFORD UNION.

THE usual weekly meeting of the Board of Guardians took place at the Workhouse on Wednesday last—The Right Hon. the Earl of Granard, K.P., in the chair.

The clerk read the minutes of the proceedings on the last day of meeting, and they were signed.

Dr. NICOLLS, in his report, called the attention of the Board to a statement set forward in the newspapers as follows:—

*To the Chairman and Guardians of the Longford Union.*

MY LORDS AND GENTLEMEN,—I beg to direct your attention to a letter recently published in the *Medical Press and Freeman's Journal*, by Mr. Denis Phelan, late Poor-law Medical Inspector, in which he indirectly imputes to you a disregard of the health of the poor in your workhouse, and in the same manner attributes to the Poor-law Commissioners a lax and negligent supervision. He goes into long and jumbled statistics to bear out his views, which I believe to be incorrect. I feel that my reports for the last three years are accurately correct, and challenge still further inquiry. Some three years since Mr. D. Phelan attacked my reports, and asked was there no inspector or auditor to check my inhuman treatment of the poor. Mr. Phelan then forgot that he had been an inspector occasionally visiting the Longford Workhouse for four or five

years after I adopted my non-alcoholic treatment of febrile diseases, yet he found no fault with my treatment, or management of the hospitals under my care.

MY LORDS AND GENTLEMEN,—It might be well if you would communicate with the Poor-law Commissioners with the view of having an investigation as to the correctness of Mr. D. Phelan's imputations; as for me I court inquiry, I dread it not; your dietary is as good as in the generality of workhouses, and I was the means of having it twice improved, compared with the original dietary, which was, I believe, made out by Mr. Phelan. The women and children are in as good condition as in any other workhouse, and I daresay there are as many very old men and women to be seen in your house as any other with equal numbers.—I have the honour to be, my lords and gentlemen, your very obedient,

S. NICOLLS, M.D.

The following resolution was unanimously adopted :—

“Resolved—That the Board of Guardians of Longford Union, are perfectly satisfied with the manner in which the Fever Hospital patients are treated by Dr. Nicolls, their medical officer, and that the remarks made therein by Dr. Denis Phelan, published in the *Medical Press* of the 8th May, 1867, and *Freeman's Journal* of the 20th May, 1867, are unfounded and uncalled for.”

## Reviews.

THE IRRITABLE BLADDER: its Causes and Treatment. By F. J. GANT, F.R.C.S. Second Edition. London: Churchill and Sons.

WE have been much interested and instructed by reading Mr. Gant's clearly written little work. An important feature in the book is the way in which practice is based upon sound and extensive pathological knowledge. This remark applies not so much to the special treatment of irritability of the bladder (which, by the by, is not so fully given as we should have expected), but to the treatment of diseases which are at all connected with, or are likely to induce that malady. The faults in the mode of living where civilization exists are largely discussed, and rules laid down for the prevention of their consequences by dietetic and hygienic means. The third section of the work, which is devoted to the detection and treatment of the different diatheses and urinary deposits is instructive as a whole, but we must disagree with the author's views with regard to phosphatic urine, and express our surprise at his use of the term “phosphatic diathesis,” which we think is, to a great extent, exploded.

A less special title might have better agreed with the general character of the work, and, therefore, we recommend our readers to peruse it, not so much for the treatment of irritable bladder as for a clear insight into the pathology and non-surgical treatment of urinary diseases.

ON HAPPINESS: its Relation to Work and Knowledge.

By the late Sir JOHN FORBES, M.D., F.R.S., Physician to Her Majesty's Household. London: Simpkin, Marshall, and Co.

THIS is a second edition of a lecture delivered before the members of the Chichester Literary Society and Mechanics' Institute, some years ago, and which was published, in the first instance, at their request. The subject of it, accompanied by the living voice, must have made a powerful impression upon the audience, and cannot fail, from the manner in which it is treated, to interest the general reader, by showing him that he may derive pleasure—even happiness—from those very things which he is apt to look upon with ill-humour, and to consider the hard necessities of his existence. Work, and the attainment of knowledge, which often press heavily on the individual, and sometimes sink him down into despondency, may both, under certain conditions, not only minister to his wants, but become a source of real and lasting enjoyment to him. The author clearly shows in what manner this may be done. He defines happiness; explains in what it consists; refers to the faculties with which the Creator has endowed us, and considers that these two are mutually dependant the one upon the other; that is, that the proper and legitimate exercise of all his powers is the constant and copious well-spring of enjoyment for man.

In proof he refers to our bodily frame. An examination of

its exquisite machinery, he says, confirms these general views. We see how each function is related to another; how they all help each other; and how their natural action is attended by gratified feelings. He admits that they may be abused, and that ill-health or unhappiness is the consequence; but he thinks that in a normal condition they may almost always be made a source of enjoyment to us. He remarks :—

“If all men were fully aware of what constitutes the due and moderate exercise of their faculties, and if they were permitted by the conventional usages and restraints of our artificial modes of life to regulate their conduct accordingly, and had the courage and constancy to do so under the guidance of their reason, I believe that they might pass through their allotted period of time, free from most of those maladies which now so grievously interrupt their comfort and usefulness, and so greatly abridge the natural period of their lives.”

Next he proceeds to the mind, and glances rapidly at its several faculties, those most obviously connected with the bodily organs, and those which constitute man a moral and social being. These, especially the perceptive and reflective, are capable of unbounded activity, which is seen in the child, and equally in the boy, and which follows him into manhood, prompting him to whatever he undertakes, and yielding him, in the employment of those powers, the happiness they were evidently designed to give. All this he illustrates by a reference to facts; to the personal experience of his hearers; and to the several classes of mankind; thereby proving that a great part of the happiness enjoyed by men is derived from what is usually termed *work*, and that “its amount is proportioned to the activity of the exercise (under due limitation) and the number of the faculties so engaged.”

He takes occasion, particularly in this part of his address, to refer to the labouring population, which forms one of the most important classes of the community, inasmuch as every other is more or less dependant upon it. Very few of the means of enjoyment come within its sphere, and we give a quotation showing the views of the writer on this point :—

“A labourer's life, framed according to the *ideal* of it, which might be deduced from the principles discussed in this lecture, ought to be a happy one; as it ought to supply, or might be made to supply, in abundance, all the materials requisite for the production of happiness.

“The only conditions are—1st, That the bodily labour should not be too severe for the bodily powers; 2ndly, That its duration should not be too long within a given period; 3rdly, That it should be broken by occasional interruptions, to afford the necessary relaxation to the muscular system.

“It forms no part of my present office to inquire whether or not these conditions are fulfilled in the actual state of society. It will be more in accordance to consider what I believe to be the main cause why the actual state of the labourer as to happiness, is so far below that of the ideal one just sketched.

“The cause I believe to be ignorance, or the want of knowledge, and would be almost as operative as it is now, even if we could truly say (would that we could!), that all the conditions above enunciated as requisite for making labour suitable, were exactly fulfilled. From want of knowledge, or, to express my meaning more accurately, from want of mental cultivation, the labourer is at present deprived of half the pleasure that should be the accompaniment of his bodily labour, and of much more than half the pleasure that ought to be his share in the hours of relaxation. It is, indeed, most melancholy to think that there should exist in any civilized nation, a large proportion of the population whose enjoyments can scarcely be said to partake of a mental character at all, or only of the lowest degree to which this epithet can apply. The subject is too painful to dwell on: but it is one, I hesitate not to say, which is a blot on the escutcheon of humanity itself, and, next to actual slavery, cries the loudest for redress. That the sole remedy to be found for such a giant evil—education, should be withheld for a single day, while civilized, and instructed, and Christian men are debating over trifles—trifles, surely, when compared with the great thing at issue—is what requires to be seen and heard to be believed.”

The lecturer then guards his hearers against the mistakes which are made by men in the pursuit of happiness, chiefly as regards the employment of their powers, and points out the best means of regulating and exercising them, so as on the whole to realize the greatest enjoyment they were designed to give. And lastly, he considers the aid afforded to the cause of human happiness by institutions such as he was addressing.

They provide for the exercise and improvement of the mental faculties; they furnish the means of rational amusement; they convey knowledge, and especially scientific knowledge; all which points are presented by the lecturer in his own impressive way, and he concludes, by a reference to himself, for the encouragement of the younger part of his audience as follows:—

“And now, my young friends, I turn once more to you, begging pardon of your seniors for the egotism in which, on your account, I am about to indulge. But knowing well how much more what may be called a *living illustration* of a fact or principle impresses the mind, than a mere didactic enunciation or even demonstration of it, I wish you all to understand that what you have heard to-night is, in some respects, a transcript from the book of my own life. In no slight degree, owing to the practical influence on my mind of the principles enunciated, my life has been, thank Heaven, a happy one; inasmuch, that I am prepared to say with the great Franklin, that if the impossible could be made possible, and it were offered me to begin my mortal career anew, I would not hesitate to accept the boon, desiring no other alteration in its course and quality but the correction (as Franklin said) of those *errata* of conduct which, on looking back, I regret to see disfiguring not a few of its otherwise fair pages.”

### THE RECENT EPIDEMIC IN DUBLIN.

IN our present number we present our readers with the conclusion of our report of the important debate on this subject. We say advisedly *important debate*, because the epidemic had taken such hold on the public mind as to lead to a pointed question being put to Lord Naas in the House of Commons; and this question was none other than whether the “Black Death” had re-appeared in Ireland?

In our number for the 29th of May we gave, in a leading article, a summary of the literature of this subject which had previously appeared in our columns, and we may now briefly recite the names of the contributors of the papers in the order in which they were published—viz., Drs. Darby, Lyons, Banks, Little, Ridley, Benson, jun., and Belcher. In that article we refrained from expressing any opinion on the nature of the disease until it had been fully investigated by the Medical Society of the College of Physicians of Ireland, and the reader

who may refer to our numbers for the 29th May, the 5th and 12th June, and also to our present number, will find in them further important papers or speeches by, or communications addressed to, the following gentlemen:—Surgeon-Major Cogan, Dr. Gordon, Censor of the College of Physicians; Dr. Lyons, Dr. John Hughes, Surgeon Haverty, 52nd Regt.; Mr. Croly, F.R.C.S.I.; Drs. Stokes and Hudson, Dr. Athill, Registrar of the College of Physicians; Dr. Darby, Dr. Warren Crooke, Dr. Belcher, Censor of the College of Physicians; Professor Law, Dr. Quinlan, Professor Aquilla Smith, Dr. M'Swiney, Dr. Bennett, Dr. Grimshaw, Dr. Little, Dr. Henry Kennedy, Dr. Hayden, Dr. Moore, V.P. College of Physicians; Dr. T. More Madden, Professor Banks, Mr. Fleming, and Dr. Herbert, 85th Regt. Besides all these, will be found the admirable summary of Dr. Stokes, of whom it may well be said, “*nil tetigit quod non ornavit*,” and who may be looked on as a peculiarly representative man at this juncture, seeing that he combines in his own person the offices of Physician to her Majesty, Regius Professor of Physic in the University of Dublin, President of the Irish College of Physicians, and of its Medical Society, and President Elect of the British Medical Association; while he is a Fellow of the Royal and other learned societies, and holds the University Doctorate at Oxford, Dublin, and Edinburgh.

The “*Consensus Communis*” of the Medical Society of the Irish College of Physicians, has pronounced that there recently has been a strange epidemic in Ireland; that the disease in question is *not* the “Black Death;” and that it is not to be called by that most misleading and terrifying title. Further, the general opinion seemed to incline to the view that it was a form of fever in which the cerebro-spinal affection was a secondary disease; that it was not ordinary typhus or measles; that it was blood-poisoning; and that there was no reason to say that it might not be of a contagious character. The President also observed, “that in some of the worst cases the symptoms of spinal arachnitis were absent, and if, as some supposed, the ecchymosis and eruptions were due to the disturbance of the nervous centres, they should have found, in the worst cases of the disease, the greatest amount of lesion, but the fact was not so. But [further observed the President], although this disease of cerebro-spinal arachnitis had been naturalized amongst us for years, it was only during the last year that the disease, marked by this singular eruption, had occurred.” Finally, the President said that, in his opinion, “this was a disease of the blood of an essential nature, and that the cerebro-spinal arachnitis was unable to explain it.” He proposed, with apparently general consent, to call it “Malignant Purpuric Fever.”

We have mentioned the President's views specially,

and we forbear to mention the opinions of others, because we could not, in the space at our disposal, specify the views of all, and we do not wish to make any selections. It was, however, apparent that three views of the nature of this disease were advanced. One, that it was a malignant spotted fever; a second, that its essence was a cerebro-spinal arachnitis; and the third, that the two diseases co-existed, the one being superadded, as it were, to the other. The generally rapid and fatal nature of the cases was admitted, and, we may add, that while the epidemic has by no means disappeared from Dublin, where we saw a case of it a few days ago (and one which went far to prove its contagious nature), yet its mortality has diminished according to that general law which seems to hold good with all epidemics; and by virtue of which those first visited mostly die, and those who have the fortune to be the last visited, mostly recover. We may call particular attention to the valuable historical information supplied by Dr. A. SMITH, as to the existence of the "Black Death" in Ireland, an alleged fact almost unknown to HECKER, and which, as was remarked by Dr. MADDEN, seems to have been wholly passed over by the writers of the "Annals of the Four Masters," the standard authorities in ancient Irish history.

On comparison of the reports which we now conclude with the reports of the Medical Officer of the Privy Council respecting the epidemic called cerebro-spinal meningitis, lately prevalent in parts of Northern Germany, and about the Lower Vistula, we must express the opinion that the view of the recent epidemic in Dublin, taken by Dr. Stokes, is most probably correct in its essence, and that the disease in question was not unknown to Cullen, Mason-Good, and other standard writers, as a blood poison called by various names, such as "febris inflammatoria putrida," "typhus scorbutica," and "febris scorbutica." Indeed, the last-mentioned name may perhaps fairly be applied to it, judging from the clear description of the affection so designated in the learned work of Daniel Sennertus "De Scorbuto," published in 1654.

#### THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

WE recorded, in our issue of the 5th inst., the assembly of the Fellows of the Royal College of Surgeons in Ireland, for the election of their Council for the ensuing year, and referred to the fact that the outgoing Council had been replaced in the administration of the College, although, in addition to the ex-Councillors, nine Fellows offered themselves to the Fellows for election. We think it right now to review this decision, not only in reference to the simple facts, but to views entertained and expressed by certain of the Fellows, in respect

to the constitution of the Council. The unanimity which prevailed at the previous meeting of the College, when the Annual Report was presented by the Council for the consideration of the Fellows, taken with the fact that a week later the charge of the Collegiate interests was confided to the same gentlemen, may be accepted as a vote of entire confidence in the Council, and as such, calls for some very forcible reasons why any of its members should be displaced to permit of the substitution of another Candidate.

The view which the Fellows of the College entertain, and in which we entirely concur, is that the first and paramount consideration is the maintenance of the College in a state of efficiency as an Educational body, and the sustainment of its qualifications at the highest standard possible under existing circumstances. If the Council of the College have proved their desire and their power of attaining the result, it should be for some very important object that its constitution should be disturbed, or its unanimity interfered with. We cannot, therefore, subscribe to the principle that Councillors who had secured an essential experience in the management of the College ought to retire to admit any gentleman, whatever his social or professional qualities may be; or that, in a selection of such vital importance to the interests of the College, the principle of rotation is a good reason for disturbing the integrity of the Council. The candidate who combines a disinterested judgment, a mature experience, and an earnest desire for the welfare of the College, possesses qualifications superior to those of party, and certainly superior to the simple claim of inexperience which seems to guide the votes of certain electors.

In enunciating this principle, we recognise, of course, the validity of the argument, that when the qualities which we have indicated can be obtained, every section of the College, and every important interest amongst its members, ought to be represented in the Council—a principle which is universally accepted by all classes. We simply combat the idea that any candidate should be selected simply because he has not previously served.

These observations are suggested by the fact that the non-acceptance of two provincial candidates was interpreted as a slight to the country Fellows generally, and such an opinion was publicly expressed by one of those gentlemen, and we take the occasion to deprecate that interpretation, and especially the language in which it was put forward. We can conceive no course more injurious to the College itself, or more fraught with danger to its efficiency than that which has been pursued, of making a distinction of interests between the Metropolitan and Provincial Fellows. Such a line of argument can tend only to the introduction of two rival factions

in the College, a result which can serve no one's purpose but that of the few who raise the cry. We venture to declare that the Metropolitan Fellows have not only declared, but proved their desire for the assistance of their provincial brethren. There are, of course, obvious circumstances which must prevent any large number of country Fellows from offering themselves for election, or being very regular in their attendance at the Council, and this fact gives a colour to the attempt to prove that their co-operation is unwelcome to their metropolitan brethren. We venture to repudiate such a conclusion, and to point to the constitution of past Councils in evidence of the fact that the provincial Fellow who occupies a position such as enables him to accept and fill the office of Councillor, runs even a better chance of being placed in that position, than his metropolitan *confrère*. The good sense of the provincial Fellows will see the propriety of submitting the problem to a practical solution on the first fitting occasion, instead of receiving from any individual candidate a statement which it will be easy to prove is groundless, and which is fatal to the good feeling which ought to exist between all co-members of the College.

#### THE APPOINTMENT OF MEDICAL ATTENDANT TO THE MOUNTJOY PRISON.

DURING the past few days a rumour has gained currency that the Government contemplate not filling up the post of Visiting Physician to the Female Convict Prison, rendered vacant by the lamented death of Dr. Banon, but appointing a Resident Medical Officer instead.

We are convinced that, in thinking of this arrangement, the Government are actuated simply by a desire to do what is best for the prisoners, and we can easily understand that, on a superficial view, many plausible arguments will suggest themselves in its favour; we are certain, however, that if carried out they will soon see reason to regret it. Never having ourselves had an opportunity of becoming familiar with the duties of the situation, we have made some inquiries, and, as far as we can ascertain, they are these:—The medical attendant has to visit daily the patients in hospital and prescribe for them; he has to examine all those prisoners who complain of illness, to ascertain whether they are really ill or only malingering; he has to see those who, for some transgression of the rules, have been placed on bread and water in the punishment cells; and lastly, he has to offer such suggestions to the authorities as his professional knowledge may enable him to give as to the diet, labour, lodging, and general treatment of the convicts—the object being to punish criminals in as perfect accordance with their sentence as possible, to interfere as little as possible with the terms of that sentence, and yet to see that their physical health and mental integrity are not compromised. The man to whom the discharge of such duties is committed should possess not only a thorough acquaintance with his profession, but he should have that knowledge of human nature which constant intercourse with society can alone supply, that good sense,

and tact, and temper, and freedom from whims and crotchets, which make the successful practitioner in the ordinary walks of the profession. If a visiting attendant is again appointed, the Government will have no difficulty in finding some Hospital Physician or Surgeon, who enjoys the confidence of his brethren and the public, in the post; but if, instead, they seek for a Resident Medical Officer, they must content themselves with some one whose qualifications, or rather whose want of qualifications, unfits him for the open field of professional competition, and who seeks a post where his inferiority may conceal itself. Under the contemplated arrangement, it is true, the medical attendant of the Male Prison will visit the Female one and supervise, we presume, the resident official. In Dublin we believe there is no one who has greater capacity for work, and better habits of business, than Dr. McDonnell, a gentleman who, despite his numerous engagements, has found time to distinguish himself highly in the difficult and too little cultivated path of original experimental research. But we presume that if visiting attendant to both prisons, containing, independent of their numerous staff, one thousand human beings, he could only be expected to see those who were actually in hospital, and the more delicate and difficult, and equally important duties, would of necessity be committed to a man who, whatever his original character and qualifications, could not long continue to look at things with his own eyes, but would gradually fall into the opinions, whether right or wrong, of the prison officials. The public look with a certain amount of suspicion on the Convict Establishments, immured within their walls hundreds of men and women, for whose crimes against society is not itself quite irresponsible. See two persons, and but two, who are not part of the prison staff—the chaplain and the physician—and the public have invariably felt that these two men, who were part of themselves, who had a reputation in ordinary life (as they should have) for independence of character, sagacity, and humanity, would not be parties to anything which the laws of the land did not sanction. We feel no hesitation in making these remarks, because the prison, the appointment to which is now under consideration, is one, against the management of which there has never been the slightest complaint, but there have been complaints against other convict prisons, and the evidence of the Medical Officer has always been received by the public as the testimony of a man who, having the advantage of full knowledge of the discipline and treatment of the criminals, was not yet mixed up in such a way with the department as to render him interested in screening abuses, if they existed. We sincerely hope, therefore, that the Chief Secretary, whose sole object, we are convinced, is the good of the criminals, will see the expediency of continuing the present arrangement.

#### Notes on Current Topics.

UNIVERSITY OF CAMBRIDGE.—Mr. Danby of Downing College, who was first in the Natural Science Trips in 1864, has been appointed Lecturer in Natural Science in Trinity College. This is the first step towards the teaching of these sciences in that great college, and, we doubt not, will be attended with very good results. Mr. Higgins, who obtained one of the Natural Science Scholarships in Sidney College, has just been elected to a Natural Science Scholar-

ship, of the value of nearly £100, in Downing College. The examination was open to Undergraduates of Oxford as well as Cambridge. Mr. Douglas and Mr. Anningson, of Caius College, has obtained the Mickleburgh scholarship for proficiency in Chemistry and Anatomy in that college. There will be an examination in Natural Science at Sidney College on October 8, for two scholarships of the value of £40 a-year each. It will be open to all persons who are not members of the University. Further information may be obtained from the Rev. J. C. W. Ellis, tutor of the college.

**CHOLERA IN LONDON.**—Two cases of Asiatic cholera are reported as having been admitted into the London Hospital last week, one of which recovered and the other died in ten hours.

**EAST LONDON WATER SUPPLY.**—Captain Tyler has been engaged, under the instructions of the Board of Trade, in inquiring into the quality of the water supplied to the metropolis by the river Lea. This we have already noticed, but in his report he discusses at some length whether the polluted condition of this stream was the cause of the fearful mortality from cholera last year in the east of London. He considers that it affords a "case of grave suspicion," though he cannot say that this water was the "principal cause" of that terrible epidemic. Leaving the river and the reservoirs of the company, he proceeds to the localities where the water is used, and here he finds a state of things which would hardly be believed. At Butler's buildings 250 people were living in fourteen houses, with less than a gallon of water each per day. Nearly the same deficiency was found in other places, and instead of proper cisterns for the water, such things as butter-firkins, tar-barrels, wine-butts, were used in all conditions of filthiness, leakiness, and rottenness, which must contaminate the water as soon as it leaves the pipes. Besides this he found 500 cases where there is only one service pipe for four or more houses. All this, which must interfere with the health and well-being of the neighbourhood, he considers the landlords responsible for in great measure, not excluding in some instances the water company; while in all he blames the parish authorities, who have the power, under the Metropolitan Water Supply Act, of remedying these evils.

**HONOURS FOR MEDICAL MEN.**—The feeling of the English people appears to be against the multiplication of orders of honourable distinction, but it should be remembered that almost an exclusive monopoly of such dignities is enjoyed by one class. We have the Orders of the Bath, the Victoria Cross, and the Star of India, as incentives to valour, but we have no acknowledgment whatever but an occasional baronetcy, for the equally arduous and infinitely more useful public services of professional men. The law, it is true, has the substantial pecuniary reward of the Bench as a goal to be reached, but the self-sacrifice, the talent, or the labour of medical men, can look to no better public recognition than the earning of fees. A doctor begins as a student, labours as a doctor, and dies as a doctor, with the same honour, as far as the public are concerned, no matter whether his career be one of lazy obscurity or uninterrupted service to the public. The presentation of the decoration of Grand Officer of the Legion of Honour to M. Nélaton, for his attention to the Prince

Imperial of France, suggests these considerations. Can any one doubt that M. Nélaton prizes such an honour more than fees, or that every medical man who reads the record of the honour will experience an emulative spark. Why is it that we have nothing better to look forward to than monied obscurity?

**THE BRITISH PHARMACOPEIA.**—It has been determined to distribute copies of the last edition of the Pharmacopœia to foreign learned societies, with the view to afford opportunity of discussion on the composition and action of remedies.

**COMPULSORY VACCINATION IN IRELAND.**—The Ballinrobe Guardians afford a cogent illustration of the unsuitableness of such a tribunal to carry out the sanitary enactments, which, in many instances, have unwisely been confided to them. It is not surprising that a saving of three halfpence in the pound in the local taxation, should be a grander object to such custodians than the saving of life from small-pox, and we trust that, in future legislation in such matters, the mistake will not be committed of confiding its enforcement to such hands. The Ballinrobe Guardians have been called upon by the Poor-law Commissioners to exercise their powers under the Vaccination Act, and have replied by the following resolution:—

That this Board feels that it would be unjust towards the heavily taxed ratepayers of this union to impose upon them any portion of the costs attendant on prosecutions under the Vaccination Act, more particularly as the ratepayers are suffering severely from lately increased taxation, chiefly attributable to the expenses of the Medical Charities Act, while the poor generally complain of the little benefit they derive from a system which has inflicted upon them heavily additional taxation. That this Board, therefore adheres to the resolution passed on the 23rd ultimo, and declines to institute proceedings without a guarantee from the medical officer.

REPORT OF THE COMMITTEE  
ON THE  
VISITATION OF EXAMINATIONS.  
SUBMITTED TO THE MEETING OF THE  
GENERAL MEDICAL COUNCIL OF EDUCATION  
AND REGISTRATION.

THE Committee, in terms of the reference to them by the Council, having read over and carefully considered the whole of the Reports of the Visitations of Examinations for the last two years, beg now to make such suggestions, founded on the various Reports of the Visitors, as appear calculated—

1. To remedy defects in particular Examinations, and
2. To improve generally the Examinations for the Licence to practise medicine and surgery.

The Committee will first make a few comments on the reports of the visitors, under the heads of the several Licensing Bodies, and will subsequently refer generally to some special matters which have arisen out of the consideration of the reports.

SPECIAL SUGGESTIONS.

I. THE ENGLISH LICENSING BODIES.

*The Royal College of Physicians of England.*

The Committee observe that this College have discontinued their own preliminary examination in Arts, and now require that every candidate for their licence should produce evidence of his having passed one of the preliminary examinations recognized by the Medical Council. It is probable that their example will be gradually followed by the other licensing bodies, other than Universities; if so, it

will be necessary that the Medical Council, in this and in other similar cases, should take care to see that the recognized Examinations in Arts include all the subjects required by them, and are in other respects deserving of recognition. But this subject belongs rather to the Committee of the Council on Preliminary Examination than to this Committee.

The Committee observe that, in the professional examinations, at each table, only one examiner, who may have been the teacher of the candidate, without any Assessor, examines the candidate on each subject, and gives his decision separately, and not necessarily after consultation with any other examiner. The Committee think it highly desirable on all accounts, that there should always be present at each table at least two examiners, who may decide upon the merits of the candidate after consultation. The same remark applies to the examination of some other bodies.

It appears that the anatomical examinations are conducted without the aid of anatomical dissections and preparations. Such an examination cannot be an efficient test of the anatomical knowledge of a candidate, and requires to be amended.

The Committee observe that no separate decisions are given in the written, the oral, and the clinical examinations. They consider it preferable that each should be judged separately.

#### *The Royal College of Surgeons of England.*

In the report for last year the visitors stated it as their opinion, that the College examinations would be improved were the physiological examinations made more extensive, and were the surgical examinations to include a practical examination in surgical appliances, bandaging, &c. This year the Committee are glad to observe that the College have given effect to the recommendations of the visitors. The anatomical and physiological examinations seem now to be very efficient. The same may be said as to the surgical practical examination, though, perhaps, it is capable of being extended still further by causing the candidate to trace on a living man the lines of incision in amputations, deligation of arteries, &c. It would be desirable, too, were it practicable, to introduce operations on the dead body. It would also be extremely desirable to have clinical surgical examinations introduced into the College of Surgeons' examinations as is now the case with many of the licensing boards. A difficulty may be found in the large number of candidates to be examined; but in London, where the hospitals are large and numerous, some arrangement might possibly be made by which each candidate might be made to show in one or more cases his knowledge of diagnosis. The matter is worthy of the attention of the College of Surgeons, and as they have already introduced clinical examinations into their fellowship examinations, they will doubtless, when possible, extend them to the candidates for their licence.

#### *Society of Apothecaries.*

In the reports of 1865-6 the visitors made various suggestions, and the Committee find, from the reports of 1866-7, that the Society have carried them out almost in their integrity. The Committee trust that the introduction of Clinical Medical Examinations will be also eventually adopted by the Society.

The reports concerning the Universities of Oxford, Cambridge, and London, require no remarks.

#### *The University of Durham.*

The professional examinations are satisfactory, and to be noted especially for their practical character. The preliminary examination, as at present conducted, does not seem satisfactory. It does not include the requisite number of subjects, and in some instances the questions are not up to the standard the Council desires to see. Dr. Embleton stated to the Committee that he was sure the University would improve this examination before next year.

## II.—THE SCOTTISH LICENSING BODIES.

### *University of Edinburgh.*

The Committee need only observe that the Clinical Medical and Surgical tests, introduced of late years into the examination of the University of Edinburgh, have been carried out without difficulty and with great advantage.

### *University of Aberdeen.*

The reports of this University are satisfactory. The examinations are well carried out and are highly practical. In certain cases candidates have been exempted from oral examination on account of the excellence of their written answers; but the Committee are of opinion that the recommendation of the General Council in this matter should be adhered to, and that no candidate should, in any case, be exempted from oral examination.

### *University of Glasgow.*

The professional examinations are satisfactory. The preliminary examination in arts appears to be defective; the papers are too elementary in some respects, and the candidates appear to have been allowed to pass too easily in some instances. Professor Thomson assured the Committee that the University would take the matter into immediate consideration, with a view to the improvement of this examination.

The Committee observe that the custom of exempting candidates from parts of the degree examination, on the ground of high merit in class examination, which was commented on by the visitors of last year, has been now discontinued. The reports of the visitors on this University are defective in not including any notice of the examinations in Botany and Chemistry. The Clinical Surgical and Medical Examinations, lately instituted, are highly efficient.

### *University of St. Andrews.*

No report has been made on this University.

### *Royal College of Physicians of Edinburgh.*

The Committee regret that no visitation of the examinations for the single licence has yet been made; but they hope the Scottish Branch Council will arrange that this omission shall not again occur. It is understood that there is no practical Clinical examination at present. The Committee trust that the College will take into consideration the propriety of following the example set them in this respect by so many other licensing bodies.

### *Royal College of Surgeons of Edinburgh.*

The examination for the single licence was only reported on last year, and even then not completely. Judging from that single report, the number of written questions seems to have been too small; but Dr. Andrew Wood stated to the Committee that since last year the number of questions had been increased. The College have not hitherto instituted Practical and Clinical Surgical Examinations; but the Committee are informed that arrangements have been made for commencing them at the Autumn examinations, on a plan similar to that pursued at the University of Edinburgh.

### *Double Qualification of the Royal Colleges of Physicians and Surgeons of Edinburgh.*

The preliminary examination and the second professional examination have been reported on, and are satisfactory so far as they go; but the professional examination, to be complete, requires that practical examinations in Medicine and Surgery shall be introduced. The first professional examination has not been reported on.

### *Faculty of Physicians and Surgeons of Glasgow.*

No report has been given of the preliminary examination in Arts. The reports on the professional examination show them to be satisfactory as far as they go; but here also there is a want of Practical and Clinical Medical and Surgical examinations.

III.—THE IRISH LICENSING BODIES.

In some respects the reports of the Irish examinations are defective, so that it is difficult for the Committee to make a sufficient report on all of them. They trust the attention of the Irish Branch Council will be seriously directed to this matter.

*University of Dublin.*

The Committee observe that by Act of Parliament a Student may commence his Professional Study without a previous examination in Arts; the occurrence is rare, but the committee think attention should be called to it. The mode of carrying on the oral examination is peculiar to this university. It is conducted in class, and the committee believe cannot be so efficient as the ordinary method of examining each candidate apart. This examination is conducted in public.

The practical and clinical examinations in surgery are excellent, and the committee observe that operations on the dead body are required. There are no clinical examinations in medicine. A chemical laboratory has been recently erected by the Provost and Board of Trinity College, for the instruction of the students in practical chemistry; and Dr. Apjohn has informed us that the examinations in chemistry will henceforward be so conducted as to meet the acquirements of the students in the practice as well as the theory of the science.

*Queen's University in Ireland.*

The Committee are informed that a student may follow his professional studies for two years before passing his preliminary Examination in Arts. The attention of the University should be directed to this as being inconsistent with the recommendation of the Medical Council.

The oral examinations are reported by the Visitors to be too short. There are operations on the dead body, but there are no clinical medical or surgical examinations.

*King's and Queen's College of Physicians.*

The Preliminary Examination in Arts is left to other Bodies. It would appear that there is no written Professional Examination, but from the unavoidable incompleteness in which the report is made, the Committee are unable to form any correct opinion of the Examinations of this Licensing Body.

The examinations are open to all Fellows and Licentiates of the College.

*Royal College of Surgeons.*

There is no Report on the Preliminary Examination. The number of written questions in the First Professional Examination is small; there are only two questions in Anatomy, one in Physiology, and one in Materia Medica, and one hour only is allowed for the answers. At the oral Examination it appears that there is only one Examiner at each table, and the decisions are given, without conference, by simple "yes" or "no." The Committee have learned from Mr. Hargrave, that since the visitation, the decisions are made by marks, and that a member of the Council sits at each table with the Examiner. The second Professional Examination, in Surgery, Medicine, and Materia Medica is conducted exactly in the same time and manner. There is no mention of Practical and Clinical Medical or Surgical Examinations. No Teacher is allowed to be an Examiner.

*Apothecaries' Hall of Ireland.*

No report has been made on the Examinations of this Body.

GENERAL SUGGESTIONS.

*Combination of Licensing Bodies.*

Referring to the number of Licences, the Committee are of opinion that the Council should strongly encourage every effort now being made, or about to be made, under Clause XIX. of the Medical Act to combine the Examinations of the Licensing Boards, so as to secure that every

practitioner whose name appears on the Register shall have been tested in all the branches of the Medical Profession. It is of importance that the Licensing Bodies, at present too numerous, should be concentrated by such combinations. The Examinations would thus be more easily supervised, and there would be a better guarantee for efficiency.

*Practical Examinations.*

The Committee are of opinion that Practical Examinations are highly desirable in all the subjects in which they can be employed, and that in no other way can the Examinations in these subjects be made completely satisfactory.

Under the term "practical" would be included all the Examinations in which a Candidate performs experiments or operations, or describes dissections or drugs, or performs post-mortem examinations, or examines with the microscope, or points of the like kind. It will be well however to illustrate by a Table more particularly what is meant.

SUBJECTS.	PRACTICAL WORK.
CHEMISTRY . . . . .	Actual Laboratory work.
MATERIA MEDICA . . . . .	Actual compounding of prescriptions; Pharmaceutical processes; naming and describing drugs.
BOTANY . . . . .	Recognition, and description of plants.
ANATOMY . . . . .	Dissections, and preparations.
MEDICINE & CLINICAL MED.	Examination of patients; microscopic and chemical examinations; pathological specimens.
SURGERY & CLINICAL SURGERY	Examination of patients; pathological specimens; bandaging, &c.; operations on the dead body, &c., &c.
MIDWIFERY . . . . .	Operative Midwifery on models.
FORENSIC MEDICINE . . . . .	Laboratory work, microscopical and chemical examinations.

It is satisfactory to find that less difficulty has been experienced in arranging for such examinations, than had been anticipated. The methods employed by different bodies are somewhat different, but the results in each case have been satisfactory. While the Committee express their satisfaction at this improvement, and their hope that progress in this direction may continue, they do not advise that any rule should be laid down, or suggestions as to the mode of conducting these Practical Medical and Surgical examinations, or as to the extent to which they should be carried. When the reports of all the visitations have been sent to the licensing bodies, the several methods now followed by some, will be considered by all, and the best parts of each plan adopted.

*The Written Questions.*

The Committee have been impressed with the importance of having the questions put in the most precise manner, so that the candidate may understand exactly what he is required to answer, and may be able to give precise and concise replies. They refer to the mode in which the questions are put by Professor Christison (*vide* the report on the University of Edinburgh, April, 1866), for examples of the plan which they think might be followed with advantage in many instances.

The attention of the Committee has been called to the necessity of preventing copying. Among other means, the arrangement of candidates by numbers or alphabetically has been found useful in detecting collusion.

The Committee have found it inconvenient not to have the questions attached to all the reports of the visitors, and they advise that this should be done, at any rate for next

year, in order to afford data for judging of the amount and quality of the written tests.

#### *The Oral Examination.*

The Committee recommend that not less than two examiners should be present at every oral examination of a candidate. A decision should be based on the opinions of both examiners after consultation.

#### *Uniform Standard of Judging the Results of Examination.*

In several of the reports, viz.—on the Society of Apothecaries, London, on the College of Surgeons, England, and on the University of Aberdeen, reference is made by the visitors to the advantage of some uniform standard. There may be difficulties in framing one which is free from objection; but there is no doubt that even an imperfect rule is better than none at all, and the Committee decided by a large majority that such a standard is desirable.

In making the following suggestions on such a standard, the Committee regard them as merely the means of eliciting the opinions of the licensing bodies, on a matter of great importance. In placing a scheme before them, and entering into some detail, the Committee do so merely as a basis for discussion, and in the hope that it will lead eventually, to a common action on the part of all the licensing bodies.

The numerical method of estimating the results of an examination is the most accurate and the most free from objections; it is now employed in all the Government Competitive Examinations, and is also used by the majority of the medical licensing bodies. The mode of using it, however, is different in each case; but, as the principle has been admitted by so many licensing bodies, it is believed that they will raise no objection to making such alterations as may render the results of the examinations comparable. Those licensing bodies which use such expressions as good, moderate, bad, or *optime, satis bene*, &c., not resting on a numerical basis, will, we conceive, have no difficulty in fixing a corresponding numerical value.

The method usually followed when a numerical standard is used, is to assign to each subject a certain number of marks which represents the total number which a candidate can gain in that subject if he answers the questions as perfectly as possible in the time.

But there are advantages in another plan, viz.—fixing the number of marks according to the time during which the examination is carried on, so that the total number of marks indicates at once the length of time the candidate is under examination, as well as the character of the answers.

The advantages of this, for the purpose of the Medical Council, will be best seen by an example.

Supposing the first plan to be adopted, and on the subject of surgery for example, a total of 1000 marks is allowed by all the licensing bodies, no comparison is still possible between the results; for one body may give the whole 1000 marks to an oral examination only; another may distribute them among a written, an oral, and a practical examination. In the record, however, as presented to the Medical Council, the candidates from each body may appear to have gained an equal number of marks although the examinations have been widely different in severity.

This is avoided by the system of marks for time.

Supposing 100 marks are given for every hour of written examination in surgery, 200 for every hour (or in proportion for less periods) of oral, and 200 for every hour of practical examination; the numerical record of such examination will at once show the nature of the examination, and its different parts will be comparable with each other, no matter what the respective arrangements of the two licensing bodies may be.

For example, one licensing body may choose to give, on a particular subject, three hours of written, and fifteen minutes of oral examination. The records of its marks would show 300 for the former, and 50 for the latter. Another body might give two hours written, fifteen minutes oral, and half-an-hour practical examination, the

marks being 200, 50, and 100, or the same as in the former case, only differently distributed. The parts of the two examinations are then comparable.

The plan will in fact be found to show not only the standard of proficiency, but the differences of the examinations, and it has the advantage of not fettering too much the opinions and methods of examination of the different licensing bodies.

The number of marks to be assigned to a particular time is a matter of importance. They should not be too few, or the wide differences of different candidates will not be properly indicated, they should not be too many, or they become unwieldy. The written examination also ought to have fewer marks assigned to it, in a given time, than the oral and the practical. The Committee believe that the best plan will be to assign 100 marks per hour for the written examination on every subject, leaving it to the examiners to fix the number of hours, and the number of questions in the hour, and the marks to be given to each question, it being understood that the whole 100 marks must be assigned between the questions, or be given to one question if there be only one in the hour.

In the oral and in the practical examination double the number should be given, or 200 per hour. Thus, if a candidate is under examination for fifteen minutes, he could gain 50 marks as the maximum; if for thirty minutes, he could gain 100. The Committee believe this may afford an approximate expression of the numerical relation between the respective tests of the written and oral methods.

The Committee would recommend, in the event of a numerical plan being approved of, that each licensing body should keep a book with the marks properly arranged in a form, in which three subjects only are introduced as an illustration.

This record would show at once both the kind of subjects and the time occupied in each.

With regard to the minimum percentage of marks qualifying for the licence, whatever numerical method may be adopted, the Committee consider it desirable to ascertain the opinion of the licensing bodies.

It may be objected to the plan now submitted for consideration, that different examiners will assign different values to answers. This objection is inseparable from the system of examinations, and applies to all modes of expressing results. But the mere fact of an examiner having to keep a fixed numerical value before him, will be found to be of the greatest use to himself, and, after practice, it will be found that the opinions of good examiners are singularly accordant. If also, in all cases, two examiners examine every candidate, and come to independent conclusions before final judgment, the system will soon be found to work with accuracy, and to afford trustworthy results.

#### *The Choice of Examiners.*

There is a very great diversity in the mode in which the examiners are selected by the different licensing bodies. Sometimes they are persons unconnected with the licensing body, but chosen by it to serve for a specified time from one to five years. In other cases, the professors of a university either examine alone, or with the assistance of examiners who are not professors. In other instances again a corporation appoints examiners from its own body, and these serve for various periods. There is, in fact, a great diversity in the modes of appointment, and the examiners of different bodies are necessarily persons of very varying capacity and experience. To attempt an alteration in one body without altering all would be invidious, and the Committee refrain from offering any suggestion to any particular corporation. But the Committee believe that, when practicable, the following points should be attended to in the selection of examiners:—

1. There should be some teachers in every examining board.
2. The appointments of those examiners who do not

belong to the licensing body should be for a definite period, with power of re-appointment.

The Committee have only, in conclusion, to express the hope that the reports of the visitors for next year, together with those of previous years, will be such as to place before the Council a full view of the system of examination, in all its branches, pursued by all the licensing boards. That progress has already been made in the improvement of some of the examinations since the commencement of the Visitations by the Medical Council is obvious; and it is no less obvious that much still remains to be accomplished, especially in the way of extending practical examinations in all departments.

The Committee recommend that a copy of this report, as submitted to the Council, be sent to each of the licensing bodies, with the request that they will express their opinion regarding the suggestions contained in it on or before the 1st January, 1868. The Committee further suggest that the answers received from the licensing bodies be thereafter printed and circulated amongst the Members of the General Council.

ANDREW WOOD, *Chairman.*

### JUNIOR SURGICAL SOCIETY OF IRELAND.

THE annual *coursazione* and distribution of prizes took place on the 7th, in the Royal College of Surgeons, Stephen's Green.

Dr JAMES STANNUS HUGHES presided.

Amongst those present were—The President of the College of Surgeons (Dr. Adams), Drs. Stoker, Minchin, Fleming, Baker, Macnamara, A. Jacob. Macalister, Mapother, Croly, Quinlan, O'Leary, Hewitt, Benson; Major Knox, Mr. Rickard, M'Carthy, &c.

Officers elected for the Session of 1867-8:—Council—Messrs W. Tobin, E. Blakeney, W. Geoghegan, J. W. Martin, A. A. West, J. H. Lyddon, Raye, J. Backhouse, P. Bodkin, C. G. Purcell, J. J. Marshall, R. W. Kelly. Secretary, Mr. William Tobin.

The following prizes were awarded:

Surgery—1st prize, A Pocket Case of Surgical Instruments, presented by Dr. Tufnell, awarded to W. Tobin. Ditto, 2nd Prize, a Silver medal, presented by Dr. Croly, awarded to R. MacCarthy.

Practice in Medicine—1st prize, a silver medal, presented by Dr. Benson, awarded to W. Tobin.

Physiology and General Pathology—1st prize, a silver medal, presented by Dr. Mapother, awarded to R. MacCarthy.

Chemistry of the *Materia Medica*—1st prize, a silver medal, presented by Dr. Barker, awarded to J. Backhouse.

Anatomy (Human or Comparative)—1st prize, a silver medal, presented by Dr. Macalister, awarded to R. MacCarthy.

Fractures—A prize of £2 2s., presented by Dr. J. Stannus Hughes, awarded to Mr. J. O'Brien and W. Geoghegan.

The prizes were then awarded.

Dr. Benson having been called to the second chair,

Dr. ADAMS briefly addressed the students, impressing on them the necessity of establishing for themselves a character of industry while they were still students, which would be beneficial to them afterwards when they became physicians and surgeons.

Dr. HUGHES then said—The council of this society have requested me, as one of their presidents, to distribute the prizes which have been awarded for the best paper on special subjects during the session just expired, and I have accepted the office with pleasure, believing as I do that the Junior Surgical Society is a credit to its parent, namely, the Surgical Society of Ireland, which, as you all are aware, stands second to none in the empire for the diffusion of sound practical knowledge. The Junior Surgical Society has now been in existence for five years, during which period many valuable papers have been read and discussed by the members with forbearance and gentlemanlike tone, the evident object of all being the elucidation of truth. Here, as in the Surgical Society of Ireland, debate but not discussion is discountenanced. Here there has been found from first to last an entire absence of jealousy and personality; thus the objects of the society have been fulfilled in the most satisfactory manner, proving that honourable rivalry amongst students as well as amongst

practitioners is quite compatible with friendship; and hear permit me to impress upon you that by a friendly and gentlemanly competition your success and happiness in this world as professional men shall be best secured. The business of the past session has, I am happy to say, been carried on with more than ordinary zeal, the society having held eleven meetings, at which twenty-four papers were read, the papers exhibiting strong evidences of close attention to hospital cases, as well as research and original thought. Indeed, as a rule, the style and matter of the papers have many merits to recommend them. There can be little doubt that the talent and industry exhibited at the evening meetings in this theatre during the past session must sooner or later be crowned with success elsewhere. I trust that next session even more competitors will appear in the field. The society is open to every school and hospital in Dublin; but I may be told that it is not every man who can write a good paper on any given subject. Now, to such a student I would say, with your note-book in your hand (and I never knew a man succeed in his profession who did not, as a student, note down his cases during his hospital attendance), with the best monographs within their reach, and with a due consideration of the cases before you, you can overcome many of the difficulties in your path; and, after all, as has been said by a learned author, perhaps the greatest of pleasures are the pleasures of difficulty. They are the greatest in number and degree, for we meet with nothing more frequently than difficulties; and the highest of all pleasures is the consciousness of having surmounted them, and the next best is the satisfaction of having made a gallant though unsuccessful attempt to do so. To the unsuccessful candidates I would say—persevere, and determine to fail no more, by which means you shall soon be enabled to submit to your fellow students a series of practical papers. With respect to the value of taking notes of our hospital cases, many indeed are its advantages. Thus, it teaches us a proper method of interrogating the patient with respect to the anterior history of his case and his present symptoms; it enables us to cultivate exactness in language; it adds to our experience, which, as Liston well remarks, is nothing more nor less than a collection of facts, whether gathered together in five or in fifty years; and, lastly, note-taking brings us more directly in contact with the patients—it insures their confidence, and naturally induces us to sympathize with and use our most strenuous efforts to alleviate their sufferings. With respect to the deep sympathy which should, and I hope always does exist on the part of medical men towards their patients, but which for obvious reasons should not at all times be exhibited—how often have I heard my professional brethren most unjustly abused for their apparent want of feeling towards their patient; but how truthfully and beautifully has Cowper the poet answered that uncalled for charge when, in speaking of the members of our noble profession, he describes them as

“Men who conceal their feelings, but who feel  
The painful symptoms they delight to heal.”

And here I would observe, that the best competitive paper is not necessarily the most original, but it may be the means of enforcing the opinions of others in so lucid and practical a manner, more especially when illustrated by cases in point as to merit the observations of the late justly celebrated thinker and writer, the Rev. Sidney Smith, when he says, “That man is not the discoverer who first says the thing, but he who says it so long, so loud, and so clearly, that he compels mankind to hear him.” Permit me here to allude to the blow we have so lately sustained by the sudden death of Dr. Banon, the Vice-President of the College, whose loss will long be felt by the profession at large. For seventeen years Dr. Banon was my colleague at Jervis-street Hospital, where, by his mild and gentlemanlike manner, his untiring kindness to the poor, and his skill as an operator, his memory will long be cherished by his patients and colleagues. The crowds innumerable of friends and admirers who followed Dr. Banon to his last earthly home, proved the high estimation he was held in by his fellow citizens of all ranks of life. Let us all endeavour, by following his good example, to earn for ourselves the high character he established for himself both with the profession and the public. I beg in the name of the Society to thank the distinguished President of our College and the visitors for their encouraging presence here to-night. To the Presidents of the Junior Surgical Society the council feel greatly indebted for having in their turns presided so efficiently over the evening meetings. (Applause).

A vote of thanks having been passed to Dr. Hughes, the proceedings terminated.

## Correspondence.

### POOR-LAW MEDICAL OFFICERS' ANNUITY SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some two years ago or more, I requested the attention of the Poor-law Medical Officers of Ireland, through your columns, to the expediency of establishing an Annuity Society for the widows and children of such of their members as are left insufficiently provided for, and I pointed out the arrangements that were made for a similar purpose by the Irish Constabulary Officers. As no steps have been since taken, that I am aware of, to accomplish that object, I take the liberty of again pressing the subject on the serious consideration of the Dispensary and Workhouse Medical Officers of Ireland, and I do so the more as they are now rather better enabled to contribute to the necessary fund than they were at that time, and I hope that the payment of half the cost of the medical relief, which is given through the Poor-law department, will soon increase their incomes.

As the Constabulary Officers' department is so analogous to that of Poor-law Medical Officers, I will describe what has been done by the former, having, through their kindness, been supplied with the resolutions and reports of "The Irish Constabulary Officers' Widows Annuity Society," which was formed in August, 1862, and rules adopted for its regulation.

One rule is, that a subscription of threepence in the pound on the pay of every officer, who shall join the society, be levied to form a fund, to be collected by monthly instalments for one year; and another, that the scale of payments fixed on be adopted as the annual income of the society, to be deducted monthly from the salary of each officer. By the 4th rule, these sums are to be invested by trustees for the use of the society. The 5th rule provides that, in consideration of the sums so paid, the widows of officers of *all ranks*, who shall continue to be members, shall be entitled to an annual pension of £40; if the wife dies before the husband, the £40 is to be continued to the children, until the age of eighteen, and on the widow's death, the pension is continued to the children till eighteen.

The trustees are Sir H. Browning, Inspector-General, and eight other officers of the force; and Mr. Maunsell, one of the first-class clerks in the Constabulary Office, is the Agent of the Society, the Honorary Secretaries being N. B. Galway, and W. D. Roche, Esquires. These respectable names show that the objects for which the society was formed, are likely, or sure, to be carefully attended to.

The parties that are entitled to admission into the Society are—1. All the Heads of the Department, including the Inspector-General; 2. All the Clerks in the Department at Dublin Castle; 3. The County Inspectors, and the Sub-Inspectors of each class; and 4. Resident Magistrates appointed from the force since 1858. All these number 295, in round numbers, say 300, of which the County and Sub-Inspectors constitute about 268, whose individual salaries range from £100 to £298, the majority having from £100 to £180. The *married* of the £180 class, for instance, pay £5 annually; that of the £100 class pay 30s., or 1½ per cent. The unmarried of each class pay only half as much as the married.

At the expiration of the first year, 288 had become members—175 married, 113 unmarried. This, at 3d. per pound, brought £524 19s. 7d. as the commencing fund, and the payments under the annual scale amounted to £831 17s.; total, £1356.

The second year's report shows 290 members—176 married, 114 unmarried. £903 was received, and £795 was funded, making in all £2672 then vested in Government Securities. Four members had died in the first year; in the second year four died. The receipts were £924 18s., of which £712 was funded, after payment of all expenses. Three members died in the next year; £955 was received, and £642 was funded. Since the last July meeting, eight more members died, making in all eighteen widows, one of whom died. The funded property is now £3400, and this year's receipts likely to be £1000.

These data afford much useful information to parties who contemplate the formation of any such society. They show that during the four years 172 per cent. of the members died annually, and that the funded property of this society is considerable.

The question to be considered is, how far the rules of this society are applicable to the condition of the Poor-law Medical Officers of Ireland. Last year's Poor-law Report shows that there are 785 Dispensary Medical Officers, whose salaries amounted to £70,843, with vaccination fees, £7944; total, £78,787, or an average of nearly £100 each. I hope and believe that each makes an average of at least £100 yearly by his private practice; and I think it may be safely assumed that each Workhouse Medical Officer receives as much—*i.e.*, £200 yearly.

I am unwilling to trespass too much on your space, and will reserve for another letter what I have further to offer on the subject.—I am, &c.,

DENIS PHELAN.

### ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention having been called to a return made to the Honourable the House of Commons, on a resolution moved by Mr. Squan, M.P., of the number of assistant-surgeons promoted to the rank of surgeons annually for the last ten years, I addressed a letter to Dr. Logan, the Director General of Army Hospitals, on the subject of the slow promotion of Military Assistant-Surgeons, in the hope of being enabled to give some statement—as to the prospects of young medical officers now entering the service, of promotion in any reasonable term—to the Irish Medical Association at the annual meeting on the 3rd inst.

I have had the honour, subsequent to the meeting, of receiving the enclosed letter from the Director General, and request you will have the kindness to publish it with the proceedings of the annual meeting of the Irish Medical Association in your next publication of THE MEDICAL PRESS AND CIRCULAR.—I have the honour to be, dear sir, yours very faithfully,

THOMAS L. MACKESY,  
President of the Irish Medical Association.

[COPY OF LETTER.]

"SIR,—I have the honour to acknowledge the receipt of your letter of the 25th May, and, in reply, to inform you that the subject of pay, promotion, and retirement of medical officers of Army and Navy, was recently fully considered by a committee appointed for the purpose at the suggestion of the Royal College of Physicians, and upon which that College, and also the Royal College of Surgeons, was represented by a Fellow of each.

"The committee's report, drawn up after taking evidence on the subject, has been accepted by the College and the Profession generally, as offering a reasonable solution of the points at issue between the Profession and the Military and Naval authorities, and their recommendations are now in course of being carried out.

"With regard to the returns laid before Parliament, the number of promotions in each year is not a reliable means of testing the probable rate of such promotion, inasmuch as, in such a calculation, no note is taken of casualties arising from other causes—such as death, resignation, and retirement upon half-pay, &c., all of which contribute to advance the juniors to the top of the list.

"I have to add that at present assistant-surgeons of twelve and a-half years service are getting their promotion, and that, considering they thus attain the relative rank of major, they are as a rule considerably in advance of their combatant brethren, and have, in consequence, no cause of complaint on this ground, which is not equally applicable to all other branches of the service.—I have the honour to be, sir, your obedient servant,

B. LOGAN, Director General."

### A DESCRIPTION OF SAN REMO.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As your journal has, on several occasions this year, contained articles upon the influence of climate on disease, and as I am now spending a few weeks in London, I hope you will find room for a few particulars respecting the progress of San Remo, my beautiful home in Liguria.

Among the English physicians who have resided with us, I would first name Dr. Prosser James, who has written in his "Climate of San Remo, and other Winter Stations of the Mediterranean," a full account of the mildness and healthfulness of this place, and predicted that it would become a favourite winter residence with his countrymen. This predic-

tion, derived from his personal residence in the winter of 1862-3, has already been accomplished to a great extent, and fully proves his acumen.

At present, the comforts and conveniences which that author pointed out as wanting to induce English invalids to visit San Remo are accessible.

Several lodgings in the immediate neighbourhood are available for winter visitors, and more of them are now building, so that it is easy for a stranger to choose whichever locality best suits his health. Thus the nervous, hypochondriacal, hysterical patient will find a pure atmosphere suited to his excessive sensibility, and the sight and perfume of flowers will relieve his sufferings. On the contrary, torpid and lymphatic constitutions, and incipient, tuberculous, pulmonary disease will also find airy and elevated situations. These villas are charming ones, and form a pretty garland round our town, and afford the comforts required by persons accustomed to elegant life. The public walks, in the midst of a luxuriant country, are spacious, bordered by long avenues of trees and influenced by the beauties of the surrounding nature. Lately a site in the centre of the town has been bought for an English Church, the plan of which has been confided to the architect Signor A. Cantù.

A committee has been formed for the erection of a new theatre. There is some agreeable society, and last winter there were several balls in the Count Roverizio's palace. There is a newspaper, *San Remo*, in which are published meteorological observations made daily by Chev. P. Rambaldi, president of Royal Lyceum.

There are two steamboats—"San Remo," and "Oneglia," which several times in a week sail to and from Genoa and Marseilles, so that the means of importation are easy.

In short, a real progress exists, which, under the auspices of the Mayor, Signor Corradi, and the present municipality, grows rapidly, and the great part of the population is full of hopes for a prosperous future.

The description I here offer of San Remo is poor enough. Nevertheless, in consideration of the difficulty with which I write your language, I hope to be excused. Only my love for San Remo prompts me to inform my English confrères of our progress.

G. B. PANIZZI, M.D.

London, June 12, 1867.

## CANDIDATES AT ST. ANDREWS UNIVERSITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

I WISH to direct attention to the regulations as to the necessary course of study to be pursued by all candidates, previous to their being admitted to the final examination for the M.B. and C.M. degrees at the University of St. Andrews.

The Royal Commissioners under the University Reform Act have ordained:—

"That all candidates for the M.B. and C.M. degrees—

"1. Shall pass an examination in the following branches of education, if possible, previous to their commencing their Medical Studies:—English, Latin, (Greek,) Arithmetic, the Elements of Mathematics, and the Elements of Mechanics.

"2. No candidate shall be admitted to a professional examination for either of these degrees who has not passed a satisfactory examination in at least two of the following subjects, in addition to those above:—Greek, French, German, Higher Mathematics, Natural Philosophy, Natural History, Logic, or Moral Philosophy."

This examination to take place, as far as possible, prior to commencing the attendance on the Medical Curriculum.

By the Commissioners' Ordinance, every candidate for the M.B. and C.M. degrees shall give evidence, by certificates, that he has attended, during four *anni medici*, one of each of the above courses; at least two of the *anni medici* must be attended in one of the Universities of Scotland, or of Oxford, Cambridge, Dublin, or the Queen's Colleges in Ireland. The other two *anni medici* may be passed in the Hospital Schools of London, the School of the College of Surgeons, Dublin, or under such private teachers of medicine and surgery as may from time to time be recognised by the University Court.

Attendance during six winter months on the medical and surgical practice of a general hospital accommodating at least eighty patients, and, during the same period, six months of practical anatomy, will be accounted an *annus medicus*.

Attendance on the lectures of any recognised private lecturer in Edinburgh, Glasgow, or Aberdeen, shall be held as another

*annus medicus*, if the fee charged for such courses of medical or surgical lectures is not less than is charged for the same courses in the Universities of Edinburgh, Glasgow, or Aberdeen.

Thus, after passing the preliminary examinations, and completing the four *anni medici*, by attending at least one course of prescribed lectures, the candidates for the degrees may be examined at the end of the second *annus medicus* on the first section of subjects—viz., Chemistry, Botany, Elementary Anatomy, and *Materia Medica*; and at the end of the third *annus medicus*, on the second section—viz.: Higher Anatomy, Zoology and Comparative Anatomy, Physiology and Surgery. Or on both sections at that time; and at the end of the fourth *annus medicus*, on the third and last section—viz.: Practice of Medicine, Clinical Medicine, Clinical Surgery, Midwifery, General Pathology, and Medical Jurisprudence. Or the whole three sections may then be taken—the examinations being both written and oral.

As many enter the study of the profession, neither desiring nor expecting the degrees of M.B. or M.D., to whom the cheaper fees of the private schools are inducements, they can attend the absolutely necessary amount of university classes required by the Medical Curriculum, after the preliminary non-professional examination has been passed before or during the first *annus medicus*.

1. At St. Andrews, the first University *annus medicus* can be completed by attending the six months' courses of Chemistry, Anatomy, and Physiology. Natural History, Zoology, and Comparative Anatomy, for the final examination.

2. *An. med.* either at the University of Edinburgh or Glasgow, where the hospital attendance can be had during the winter session, with, at the private schools, Anatomy, Physiology, *Materia Medica*, and Surgery; and, if with six months' Practical Anatomy, along with the hospital, this would complete the second *annus medicus* or,

If the *Materia Medica* for six months, and two three month courses of Botany and Medical Jurisprudence during the summer session, were attended in Edinburgh or Glasgow, then the second University *annus medicus* would be complete; and the candidate, if well prepared, would be entitled to pass the first professional examination in Anatomy, Chemistry, Botany, and *Materia Medica*, before the commencement of the third *annus medicus*, and all the rest of the University restrictions would be loosed.

3. If, during the third *annus medicus*, the six months' Hospital and Practical Anatomy, and the other courses of the third division were attended—Practice of Medicine, Clinical Surgery and Medicine, Midwifery, General Pathology—after passing a satisfactory professional examination on Higher Anatomy, Zoology and Comparative Anatomy, Physiology and Surgery, with a competent knowledge of all the required subjects, the fourth *annus medicus* might be spent at St. Andrews, and the final examination for the degrees of M.B. and C.M. take place; and if the examination is satisfactory, and the full age of twenty-one, the degrees might be conferred during the April of fourth *annus medicus*, or within three years and a-half from their first entering the University. But if a competent knowledge of all the subjects of Medical and Surgical Education has not been acquired, the classes on these must be continued during the fourth winter session, and the final examination on the Practice of Medicine, Clinical Medicine, Clinical Surgery, Midwifery, General Pathology, and Medical Jurisprudence. All these three sectional examinations may be passed under the St. Andrews Medical Faculty, with the assistance of those additional examiners appointed by the University Court.

I now point out to another class of candidates who may have passed the matriculation examination of the London University, from one of the affiliated provincial or the London hospital schools, for two *anni medici* ("the *annus medicus* being constituted by two courses of six months, 100 lectures each; or one such course, and two three month courses of 50 lectures each"). The other two *anni medici* could be completed by two winter sessions in Edinburgh or St. Andrews, and the M.B. and C.M. degrees, after a sufficient final examination, in the course of April, in one year and a-half after entering the University of Edinburgh; and by registering in St. Andrews, the whole three divisions of the examinations may be held by the St. Andrews examiners, according to the regulations.—I am &c.,

WILLIAM MACDONALD, M.D., F.R.C.P.E.,  
Professor of Natural History, Zoology,  
and Comparative Anatomy.

United College, St. Andrews, June, 1867.

## CASE OF CHOLERA IN DUBLIN.

WE learn with regret that a case of well pronounced Asiatic cholera has occurred on Sunday last in Pembroke-road, under the care of Dr. Peter Little, of Dominick-street. The attack was sudden and violent, and was attended by the usual symptoms of rice-water vomiting, cramps, *facies cholericæ*, and collapse. Happily the patient has survived, and is now convalescent.

## PAYMENT OF MEDICAL WITNESSES IN IRELAND.

THE Council of the Royal College of Surgeons in Ireland have had under their attention this question, and, with a view to the settlement of it by the insertion of a clause in the Common Law Bill now passing through Parliament, a deputation from that body has waited on Mr. Colles, the taxing master. It appears that the Judges in Ireland have no power to order payment to medical men as English Judges have, and in the schedule of payment, which it is proposed to insert in the new Act, the remuneration is named at not less than one guinea, and not more than three, with one guinea per day travelling expenses. The Attorney-General and Chief Secretary for Ireland have been so constantly employed that they have found it impossible to receive a deputation from the Council in Dublin, and Dr. Hargrave, Mr. Hughes, and Dr. Quinan, have proceeded to London for the purpose of having the clause introduced in the Bill, which comes on for a second reading on Thursday next. We understand there is every reason to hope that the object will be attained.

## Medical News.

**LADY MEDICAL STUDENTS.**—It seems that the judicious provision of the Apothecaries' Society requiring all ladies desirous of taking their licence to practise, to pursue their studies in the recognised Medical Schools, will not always act as a deterrent, at all events for those of them who may come from the other side of the Atlantic. A lady, it seems, is unblushingly attending anatomical lectures in Paris, in the midst of a crowded class-room, and is thus tenderly dealt with by one of the Paris Medical journals, *a la mode de Paris*:—"An American doctress is at the present time attending Professor Fort's course of anatomy. She is remarkably intelligent, young, and good-looking, and is getting on very rapidly. If there is anything remarkable about her amidst her male fellow-students, it is the unaffected impassibility which she maintains during the various descriptions which an anatomical course necessarily entails." We cannot but believe that many of the students really bent upon work must regard the presence of this pretty little dear as an intolerable intrusion.

**ST. BARTHOLOMEW'S HOSPITAL.**—The statistical tables of the patients treated in the wards of this institution during the past year, prepared by Dr. Edwards and Mr. Willett, have just been issued. The number of patients admitted was 5088. The patients remaining on the 1st of January, 1866, amounted to 527, bringing up the total number under treatment to 5615. Out of this number 3980 were discharged cured and relieved, 250 were discharged unrelieved, 277 were discharged for other than medical reasons, and 563 died. Out of the 2224 patients treated in the medical wards, 1323 were discharged cured and relieved, and 418 died. Thirty-six, or 8'61 per cent., died within twenty-four hours of admission. Out of the 418 deaths in these wards, 71 were the result of consumption, 64 were caused by diseases of the respiratory organs, 42 by cholera, 36 by albuminuria, and 29 by fever. Cancer of the internal organs contributed 23 deaths. Out of the 3391 patients treated in the surgical wards, 2657 were discharged cured and relieved, and 145 died. Thirty-three, or 22'8 per cent., died within twenty-four hours of admission. Out of the 145 deaths in these wards, 30 were the result of fractures, 23 were caused by burns and scalds, and 10 by cancer of the external organs. The following is a statement of secondary diseases which occurred within the hospital among 126 patients admitted for other diseases:—Scarlatina, 16;

typhus, &c., 15; cholera, 3; erysipelas, 31; cellular inflammation, 14; pyæmia, 17; rheumatism, 4; phagadæna, 1; gangrene, 2; and delirium tremens, 23. The report contains an elaborate series of tables recording the ages and occupations of the patients, extending over 72 pages.—*Times*.

**MEDICAL CHARITIES.**—We have great pleasure in announcing that the late John Gott, Esq., of Armley House, Yorkshire, has bequeathed £200 to the Leeds Infirmary, and £100 to the Leeds Public Dispensary. Miss Charlotte Raine, in addition to those large sums formerly mentioned as having been bequeathed by this benevolent lady, has also left £500 to the Metropolitan Free Hospital, and Joseph Cragg, Esq., has also bequeathed £500 to the Middlesex Hospital, all legacies to be paid free of legacy duty.

**THE CATTLE PLAGUE.**—We learn with much pleasure, from a letter of M. Van Thal, that the cattle plague is decreasing in Holland, the return of cases for the week ending May 25 being the insignificant number 39. It is to be regretted that we cannot report as favourably of our own country. Since our last number a meeting of the Court of Common Council has been held, and information has been received that the rinderpest is making its way among us once more. Mr. Rudkin informed the chairman of the meeting that "the cattle plague has broken out in a most virulent form almost all over the metropolis, with the exception of the City of London." The authorities are adopting measures to prevent the further extension of the plague, and Orders in Council have been issued to prevent foreign cattle being driven through the streets of the metropolis to the cattle market.

**SINGULAR FATALITY AMONG SHEEP.**—On the arrival at Leith of the screw steamer *Stettin*, on Sunday afternoon, her captain reported that of about 600 sheep he took on board at Copenhagen, 111 had died and been thrown into the sea. The weather and behaviour of the vessel were all that could be desired, yet, from some unaccountable cause, many of the sheep sickened and died. After the vessel was in the dock two of the animals were found dead, and fifteen others so weak that they had to be carried ashore. A rumour has been circulated that the sheep were suffocated by being kept too close, but the report is without foundation, for the *Stettin* is capable of carrying twice the number of sheep she had on board.—*Scotsman*.

**CHIGNONS AND COOKERY.**—According to the report of the Inspector of Nuisances for Bermondsey, an oven, situate at 65, Richardson-street, in that district, is employed during week-days in heating hair to destroy parasitic germs before it is converted into chignons, and on Sundays it is employed to cook the dinners of the poor. Who, we should like to know, is the humane and enterprising proprietor of this oven which is thus contrived "a double debt to pay?"

**THE SCOTTISH REGISTRAR-GENERAL'S RETURN** records 19,981 deaths in Scotland in the first quarter of 1867, being in the annual proportion of 25'1 deaths per 1000 of population. This mortality is above the average of the corresponding quarter of ten previous years, which was in the annual proportion of 24'6 deaths per 1000 of population. The annual mortality of the town population in the quarter ending last March, was 29'3 per 1000, while the annual death-rate among the rural population was only 17'5 per 1000. Bronchitis, pneumonia, and affections of the respiratory organs generally, have been very prevalent. Typhus and typhoid fever prevailed to a considerable extent over the country, also scarlatina, measles, and whooping cough. Cholera caused, in Scotland, 33 deaths during the quarter; 25 of which occurred in January, six in February, and two in March. In the month of January, in consequence of the severe weather, the deaths were double the usual number. In March, also, the frost was so intense, with east winds, hail, snow, and sleet, that all agricultural operations were completely stopped. The mortality in Scotland during the three months, was greatly influenced by the temperature. Thus in January, with a temperature of 31'8 degrees, there were 238 deaths daily. In February, with a temperature of 41'4 degrees, the daily deaths were 210; in March, with a temperature of 36'2 degrees, the daily deaths were 217. The mean temperature of the quarter was 36'5 degrees.

**THE AMERICANS AND THE CHOLERA.**—The Registrar of Vital Statistics of New York, Dr. Harris, has addressed to the Board of Health a letter, in which he says:—

"Since last fall the Asiatic cholera has been making progress in various countries, and both in Europe and America its smouldering infection has been rekindled in a few places. Important progress has meanwhile been made in the practical application of preventable sanitary measures to restrain and extinguish the epidemic. Waiting the completion of our full report upon these facts, the following brief summary of recent inflammation is submitted:—Several hundred scientific physicians in Europe have prepared reports upon their special investigations, experimental, microscopical, and chymical, in cholera. The grand conclusion of all the researches and all comparisons and analyses of experience relating to cholera may be summed up in these homely words—put out the sparks; remove the local causes that increase and spread the epidemic. The fact that cholera is propagated and spread by an infective poison which requires the aid of certain local factors is fully established. That it is not contagious like typhus and small-pox, and that the infective property of the excremental discharges of the sick and of persons that have been recently exposed in places infected by cholera may be completely disinfected and destroyed by certain chymical agents, is the important truth which all classes of people should understand. Scientific chymists and experimenters and all sanitary officers now agree that saturated solutions of coppers and carbonic acid are at once the best and cheapest disinfectants that can be used against cholera. In every city that is now prepared to extinguish or prevent the epidemic there has been organized a system of medical relief and house-to-house visitation, to be ready beforehand for any event. St. Louis put its excellent system in operation soon after the first arrival of a cholera patient this spring from a down-river town. The disease did not extend to a half-a-dozen persons. St. Louis now is, and is likely to remain, one of the healthiest and safest commercial towns that one can visit in America, thanks to the Board of Health. Very early in the spring the epidemic was rekindled in certain towns on the Mississippi, south of Cairo, It was conveyed many hundred miles up the Arkansas River, and to certain points north-west on the Mississippi. But recent information warrants the hope that those outbreaks have been totally extinguished. Early in April an outbreak of cholera occurred in the city of Porto Alegre, in South America, and in a few days fifty cases occurred. This outbreak is supposed to be associated with German and French commerce that is held with that disturbed region. What intercourse has been had with infected West Indian or Central American ports does not appear; and they, like the nearest European ports, are more than 3,000 miles distant, Porto Alegre being 34 degrees south of the equator, and not far north from Montevideo. About four weeks ago cholera reappeared in London and in Paris, but it is reported not to have spread to any extent. In the town of Elberfeld, near the Rhine, and about 80 miles south-eastward from Rotterdam, the epidemic appeared, and has spread to some extent. That town is in a region that sends many emigrants to New York by way of Rotterdam and Liverpool. These facts can be understood by our people without awakening anxiety or fear, for to be "forewarned is to be forearmed," and although there may be numerous cases of cholera imported from the south and elsewhere, and though there may be repeated outbreaks in the lower regions of the Mississippi, the means of sanitary protection are definite, ample, and easily applied. But wherever, in places that are ready for the kindling of the epidemic, the true means of sanitary protection are not applied, the pestilence may yet make deadly ravages. The watchword of the Metropolitan Board of Health—"Timely and active preventive measures"—should be adopted by every city and town to which the epidemic can come.

**THE CATTLE PLAGUE IN LIVERPOOL.**—From investigations made at the request of private firms in Liverpool by Professor Gamgee, and other experienced gentlemen, it has transpired that the alleged case of rinderpest at Ullet-lane, Liverpool, was not a case of that disease. It is to be hoped, therefore, that the Privy Council will at once rescind the orders which, on the report being made, they have issued for restricting the sale of cattle in Liverpool.—*Times*.

#### NOTICES TO CORRESPONDENTS.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor, at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot

be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

Mr. Harrison is thanked for his communication.

Mr. W.—We cannot undertake to introduce the subject to the parties mentioned in your letter.

C. E.—Yes, by Dr. Lane.

Chemicus.—The preparation is anything but first-class.

Several letters and important communications are unavoidably postponed.

**ERRATA.**—In the report of the proceedings of the General Medical Council, at bottom of page 5 of Supplement, for "State Medicines," read "State Medicine." On page 6, first col., for "Medico-legal forces," read "Medico-legal farces."

#### MEDICAL APPOINTMENTS.

EDIS, ARTHUR W., M.B., M.R.C.S.Eng., has been elected Physician-Accoucheur to the St. George's and St. James's Dispensary.

CHALDECOTT, H., M.R.C.S.E., has been appointed a Resident Physician's Assistant at the Middlesex Hospital, vice J. Murray, M.B.

FIELD, G. P., M.R.C.S.E., has been appointed House-Surgeon to St. Mary's Hospital.

ARMSTRONG, H. R., M.R.C.S.E., has been elected Resident Medical Officer to the Newcastle-on-Tyne Dispensary.

BENNETT, W. J., M.R.C.S.E., has been appointed House-Surgeon to the Dorset County Hospital.

STANGER, WM., M.R.C.S.E., has been appointed Assistant Medical Officer to the County and Borough Lunatic Asylum, Sncnton, near Nottingham.

MANISTY, Mr. F. S., has been appointed one of the Resident Surgeons to the Birmingham Lying-in Hospital and Dispensary for the Diseases of Women and Children, vice Seachard, resigned.

MOORE, W., M.R.C.S.E., has been appointed House-Surgeon to the West Hertfordshire Infirmary, vice J. P. Purvis, M.R.C.S.E., resigned.

SIMPSON, Mr. A. B., has been appointed a Resident Surgeon to the Birmingham Lying-in Hospital and Dispensary for Diseases of Women and Children, vice Dr. Macbeth, resigned.

THOMAS, M., M.D., has been elected Medical Superintendent of the Royal Infirmary, Glasgow.

MARTIN, ALEXANDER, A.M., M.D., L.R.C.S.E., has been appointed Medical Officer to the Combination Poor-house of Kincardineshire, situated at Stochaven.

PATERSON, J., L.F.P. & S.Glas., has been elected Medical Officer for the Parish of New Monkland, Lanarkshire, vice G. Cowie, M.D., deceased.

#### Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

##### BIRTHS.

JONES.—On the 2nd ult., at Cannpore, the wife of J. Jones, M.D., Civil Surgeon, Cannpore, of a daughter.

GRAHAM.—On the 27th ult., at Paisley, the wife of Dr. Graham, of a daughter, still-born.

HEDDLE.—On the 5th inst., at St. Andrews, the wife of M. F. Hedde, Professor of Chemistry in the University of St. Andrews, of a daughter.

##### MARRIAGES.

BLUNT—ROME.—On the 30th ult., at the British Embassy, Paris, Thomas Blunt, M.D., of Leicester, to Ann, eldest daughter of the late Joseph Rome, Esq., of Groundsdown, Staffordshire.

DENTON—WILLIAMS.—On the 1st inst., at Cheltenham, T. W. Denton, M.D., of Newbold Lodge, Cheshire, to Sarah Ellen, widow of T. Williams, Esq.

SCLANDERS—MACKINTOSH.—On the 4th inst., at Auchnacloch, Nairn, A. Sclanders, M.D., of Forres, to Christina, daughter of the late J. Mackintosh, Esq.

JEFFERSON—SQUAREY.—On the 6th inst., at Barnes Church, Horace Jefferson, M.D., of Westhill, Wandsworth, to Helen Mary, youngest daughter of the late Charles Squarey, of Salisbury.

GOGARTY—SANPESON.—On the 6th inst., at Cottingham, H. A. Gogarty, M.B., Assistant-Surgeon 52nd Light Infantry, to Emily, only daughter of the late C. R. Sanderson, Esq., of Hull.

SANDWELL—CLARKE.—On the 8th inst., at St. Anne's, Soho, E. Sandwell, M.R.C.S.E., of Charles-street, Soho-square, to Mary Jane, second daughter of J. F. Clarke, M.R.C.S.E., L.S.A., of Gerrard-street, Soho. No cards.

TAYLOR—SOTHERN.—On the 5th inst., at St. Mary Abbots Church, Kensington, J. M. Taylor, F.R.C.S., Royal Horse Artillery, to Mary Ellen Worrall, daughter of the late J. Sothern, Esq., the Priory, near Liverpool. No cards.

##### DEATHS.

BROMLEY.—On the 20th ult., at Calderbridge, H. W. Bromley, M.R.C.S.E., of Gosford, Cumberland, aged 39.

CUST.—On the 29th ult., J. C. Cust, M.R.C.S.E., of Barnard-castle, Durham, aged 50.

FERGUSON.—On the 15th inst., of consumption, at Bloomfield Cottage, Girvan, Ayrshire, Jessie Muir McCreath, wife of Alexander Fergusson, L.R.C.P., Ed., &c., aged 22—much regretted.

HOOD.—On the 2nd inst., at the Bedford Hotel, Covent-garden, D. Hood, M.D., Assistant-Surgeon, H.M. Bengal Army, aged 36.

RAMADGE.—On the 8th inst., at 12, Clarges-street, Piccadilly, F. H. Ramadge, M.D., in his 74th year.

TINKER.—On the 11th inst., at Acres Cottage, Hyde, Cheshire, Frederick Tinker, Esq., Surgeon, F.R.C.S., aged 63.

## Lecture.

## CLINICAL LECTURES

DELIVERED IN  
STEEVENS' HOSPITAL,TOGETHER WITH  
OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

REFLECTIONS ON THE CAUSES OF DROPSY.

(Continued from p. 575.)

"THE next case I shall record is one of great interest,—a case of extreme anasarca, the result of anæmia, and without organic lesion, occurring in an hospital patient. He was about thirty years of age, had never lived intemperately, and was superior to the generality of hospital patients in manner and education. His life had been spent in an office, at the desk, the nature of his occupation permitting him to take very little exercise. By long continued and frequently profuse bleeding from the hemorrhoidal vessels, he was reduced to a state of complete anæmia, and, owing to extreme debility, had been compelled to give up his situation as a clerk. When admitted into hospital he was universally anasarca. The first signs of œdema manifested themselves in the lower extremities and face; his respiration was hurried; his pulse feeble and rapid; no murmur accompanied the cardiac movements, nor was there any auricular evidence of deposition in the pulmonary cells. The urine was scanty, low in density, and not albuminous. He remained for several days in hospital, and the symptoms not being in the least degree submissive to treatment, it was determined to give exit to the fluid by acupuncture. Numerous punctures were made, during several successive days, in different parts of the body; the thin serum flowed freely; the anasarca subsided; the secretions became abundant; and the treatment ultimately issued in a complete restoration to health. His diet was gradually rendered more and more nutritious; he was allowed wine and malt liquor; and, after the operations, his medicines were iron and ammonia. I cannot avoid recording an emphatic expression used by this man. After having been twice acupunctured, and when the serum was flowing profusely, I asked him how he felt? His reply was: 'Sir, I feel greatly relieved: when I was a boy, I wept from my eyes; now that I am a man, I weep from my whole body.'

I also append the following observations, which were originally published with these cases, as they illustrate remarkably my present subject:—

"These cases illustrate the circumstances under which the operation of acupuncture may be most advantageously employed; indeed the only circumstances which give to it a permanent value. It may often be practised usefully as a palliative: rarely, however, is it a curative measure. In dropsy from organic disease it removes the tension, and enables the blood to circulate more freely, so that the medicines may act, and the effused fluid be absorbed; but the organic disease remains, and the dropsy returns. In the foregoing cases there was no organic lesion, either cardiac, pulmonary, hepatic, splenic, or renal. The tension being removed, and the medicines enabled to produce their full effect, the serous effusion was absorbed, the constitution invigorated, the quality of the blood improved, and the cure rendered perfect. Far otherwise is it in those vastly more numerous cases of dropsy, resulting from morbid change and deposition in organs essential to life; in many of these, acupuncture is a useful adjuvant in the treatment, but it cannot remove the cause of the effusion.

"Trifling as this operation is, I have seen it followed by consequences the most disastrous,—erysipelas and gangrene. In advanced cases of dropsy, when the blood is much altered,—all but disorganized,—it is dangerous to puncture the skin. I have also seen cases in which, from the perpetual oozing of cold serum, the broken-down state of the health and of the blood, each puncture has been followed by a large and foul ulcer. In other instances of hopeless dropsy, even though the patient escape these grave consequences of acupuncture, the limbs have been kept so constantly wet and cold as greatly to distress the patient and aggravate his sufferings. It requires, then, observation and judgment to distinguish the cases in which this remedy may be safely and successfully employed. It may be here remarked, that the more limpid and less dense the effusion, the more favourable is the case for acupuncture. I have observed many cases of anasarca resulting from organic renal disease, wherein it required strong pressure to produce a pit or dimple; nay more, the limbs have been so rigid as to render the joints immovable, such has been the density and solidity of the matter which occupied the subcutaneous serous tissue.

"I saw, some years ago, in consultation with Sir Philip Crampton, a very remarkable case of anæmic dropsy: the patient was about thirty-five years of age; he had been reduced by long-continued and profuse hemorrhoidal bleeding to a state of extreme anæmia. The prominent symptoms were, death-like pallor, excessive debility, langour, constant dyspœa, occasional orthopnœa, bellows murmur of the heart and arteries, universal anasarca, and peritoneal effusion. Sir P. Crampton, by an operation, put an end to the sanguineous exudation; whereupon a rally took place; and then tonics, diuretics, moderate stimuli, and nutritious diet, completed the cure."

Repeatedly I have witnessed the interesting phenomenon of red and white blood extravasations co-existing at the same time and in the same person. This occurs in purpura hæmorrhagica: the white blood extravasation, indicating the ruined state of the blood, takes place at an advanced state of the disease, and points but too surely to a fatal issue; whilst blood in its entirety is oozing in all directions from mucous surfaces, and staining with spots and ecchymoses the skin under the cuticle; the white portion of the blood, reduced to a state of the utmost tenuity, is occupying and distending the spaces of the serous membranes, both under the external skin and in the serous sacs or surfaces involving the internal viscera. The one from the mucous outlets generally escapes, whether the red blood flows from the nares, or intestines, or bronchi, or bladder, or vagina; after extravasation, it is expelled from the body—not so with white blood extravasation—into serous tissues. It is pent up; it cannot find immediate exit; hence the necessity of effecting its removal from the body, either by absorption, or by ulceration, or by instrumental operation.

The cases hitherto recorded have reference to *blood*, not to *visceral* disease. Of atonic dropsies, the first variety is the most amenable to treatment.

Dropsy, always formidable, assumes its most fatal aspect when linked with visceral disorganization. In such cases though it may often be removed, yet, the cause remaining—probably increasing in intensity—it will again and again recur; and this harbinger of dissolution at length refuses to yield to treatment, however varied. It often, however, claims the first and most important place in the adaptation of remedies. Hence the great variety of substances derived from the mineral and vegetable kingdoms which, possessed of diuretic properties, are earnestly sought after. It is a fact that diuretics must be varied: those which to-day are eminently successful will on a future day grievously disappoint expectation. Amongst diuretics, mercury holds and maintains the first place. There is, perhaps, no combination of medicine more frequently or surely to be relied upon than the diuretic compound judiciously administered—consisting in mercury, squill, and digitalis.

I shall not multiply cases of atonic dropsy, resulting from

intractable and destructive morbid action, affecting an important viscus, the normal functions of which are essential to the preservation of life. The *permanent* cure of dropsy depends upon the removal of its cause. If all treatment fail to remove the cause, the symptom, dropsy, will resist all efforts directed towards its *permanent* cure. It may often be temporarily removed, but if the cause remain, as surely as the tide which ebbs will flow again, so surely will dropsy, if the patient still linger on, reappear.

A case has but lately fallen under my observation of protracted disease of the alimentary canal: it terminated, after a long illness, fatally. For many weeks all solid and substantial food was rejected by vomiting: no articles of diet were retained except those which are lowest in the scale of nutrition, and, like an infant's food, in a highly liquid state; there was also a perpetually recurring diarrhoea. About a fortnight before the fatal termination of the disease, œdema, manifesting the signs of the thinnest serosity, appeared, though the patient had been previously, and was then wholly confined to bed, and always in the recumbent position, in the lower extremities: first, at the insteps and ankles, and, advancing hourly, reached the hips, and extended along the most dependent parts of the trunk. The dropsical distention was very great, and particularly in the lumbar region. In the superior extremities and anterior parts of the trunk, though present, it was less discernible. No doubt could exist that there was in this case organic disease of the stomach and extensive ulceration of the intestines. Everything essential to the production of atonic dropsy was in this case present.

Yesterday I took a brief note of the following case:—A gentleman, aged 64; his countenance expressive of malignant disease; food received into the stomach seems to himself not to descend; immediately on being swallowed it is rejected by vomiting; he is thus for the time relieved; the vomiting, at first slight, has lasted for four months; he is greatly emaciated; hiccups frequently; feels most easy when in bed; great debility referred chiefly to limbs; pulse very small; heart sounds feeble; urine natural; bowels regular; a soft, semi-transparent œdema fills up and distends the lower extremities, reaching half-way up the thigh.

To these many such like cases might be added. It is needless: they tend to confirm the view already put forward—namely, that the cases most apt to terminate in atonic dropsy are those which involve in morbid action the alimentary canal and its appendages.

Some persons are constitutionally, from temperament, liable to serous effusions. With such, a smaller amount of disease is capable of producing dropsy; at an earlier stage of a malady it will set in; moreover, the catastrophe of an hydropic effusion may, by general management, be either precipitated or retarded, or even averted. If the diet be well suited to the enfeebled digestive function; if the heart be not unduly stimulated by ardent liquors, by mental emotions and passions, by muscular exertions, and other such causes; and if quiet and recumbency be sufficiently maintained, these dropsical effusions may be postponed, or possibly even averted. Influenced by an opposite mode of management and treatment, it may be accelerated. This remark is applicable only to some forms of dropsy.

The rapidity with which I have sometimes observed a large effusion in a poor hospital patient to be carried off has surprised me. The influence of new and unaccustomed circumstances, the altered diet, the quiet and recumbency, have appeared to have been mainly instrumental in effecting this great alteration in the functions of the vascular system.

Some weeks ago a poor woman, affected with aneurism of the arch of the aorta, was admitted into Steevens' Hospital. The tumour pulsated vehemently and prominently. She suffered intensely from neural pains, shooting from the sternum to the spine, and along the left arm. She remained several weeks in hospital, and, feeling herself much relieved, she returned home. At the end of a month

she was re-admitted. In the interim copious effusion had taken place into the infra-cutaneous serous tissue of the thorax and arm, on the left side. Whilst at home she was stinted in food, and it was not only scanty but coarse; she was also obliged to work. After her re-admission she remained quiet and recumbent, and her diet was carefully regulated. Scarcely had ten or twelve days elapsed until every trace of the effused fluid had vanished. It had so happened that the medicine ordered for her she had not taken.

In the cure of dropsy, treatment should not be restricted to medicine; systematic and dietetic treatment should never be neglected. I have said that dropsical effusions are influenced by temperament; it is also true that they are influenced by previous habits and manner of living. As far as my observation has reached, I should be disposed to assert that those *sudden* effusions into the ventricles of the brain, and also those into the pleural and peritoneal sacs, which occur in cases of renal, and sometimes in cardiac, diseases, are much less likely to occur in the atonic than in the obstructive and inflammatory varieties of dropsy.

## Original Communications.

### A CASE OF COCCYODYNIA CURED BY OPERATION.

By GEORGE H. KIDD, M.D., F.R.C.S.I.,

ASSISTANT MASTER TO THE COOMBE LYING-IN HOSPITAL, ETC.

(Read before the Dublin Obstetrical Society on June 8th, 1867.)

COCCYODYNIA is the name proposed by Sir James Simpson for a painful affection of the coccyx, of not uncommon occurrence, but not recognized or described in books, till he gave an account of it in the *Medical Times and Gazette* for 2nd of July, 1859. Since then Erichsen, in the fourth edition of his "Surgery," has given a short account of it, founded on Simpson's paper; and Dr. West has described it in the third edition of his work "On the Diseases of Women" under the more correct, but not so convenient term of coccygodynia, the name suggested by Scanzoni in a very elaborate paper published in the *Wurzbürger Medicinische Zeitschrift*, and which has been followed by Dr. West in his observations. In this paper Scanzoni gives an account of twenty-four cases, but as many of them were accompanied by various affections of the uterus and neighbouring organs, and the pain ceased on the removal of the associated disease, they can scarcely be considered cases of the affection described by Simpson.

The leading symptom of the disease is, according to Simpson, pain in the region of the coccyx experienced by the patient whenever she sits down and rises, and sometimes while she remains in the sitting posture. Most of the patients affected with it are obliged to sit on one hip, or with only one side resting on the edge of a chair, or with the weight partially supported by a hand on the chair, and they are rendered sometimes very awkward and miserable in consequence, some of them actually dread sitting down, so great is the pain then felt, and not only so, but the pain is, in many cases, aggravated or renewed whenever it becomes necessary to resume the erect posture. There are other movements of the coccyx besides that are liable to be attended in such cases with pain. Thus, some patients have pain with every step they take in walking, while in others the movements of progression excite no uneasiness whatever. Others, again, feel the pain most when the bowels are being evacuated, or under any circumstance in which the sphincter or levator ani, or the ischio-coccygeal muscles are called into action.

The pain is not in every case very acute or intolerable and varies as to its severity in the same patient at different periods. It is always increased by pressure on the coccyx, and more so when the pressure is made from the point upwards; and it is also increased by moving the coccyx

with the finger, but the kind of movement that most aggravates the pain differs in different cases.

The pathological cause of the pain, according to Simpson, is disease of the coccyx or of the coccygeal joints, or inflammation of the surrounding fibrous tissues, arising in general from some injury inflicted during labour, or in some other way. In one of his cases it was caused by a fall from a horse. Two of Scanzoni's patients referred it to frequent long rides on horse-back. South mentions the case of a gentleman who fractured his coccyx by sitting down suddenly on the corner of a snuff-box, and who was ever afterwards obliged to wear a pad on each tuber ischii to keep off pressure.

In many cases the disease cannot be traced to any definite cause. One of Simpson's patients attributed it to sitting for a long time on damp grass. It may occur in the male or female, in the married or single woman, but the most frequent cause is injury to the part during child-birth. Of Scanzoni's twenty-four cases, eleven of the patients attributed the disease to this cause. When the diseased condition is once established every movement of the muscles, or structures connected with the coccyx, causes pain, and prevents the part from regaining a healthy condition.

For the treatment of the disease Simpson recommends the subcutaneous division of all the muscles and fibres connected with the coccyx, so as to isolate it and allow it to remain at rest, which he has found to give almost immediate relief in most cases, but in some it has failed, or the relief has only been temporary, the pain returning after a time. In one of the cases detailed in his original paper this occurred, and he subsequently removed the coccyx entirely, and I find, by a notice in the *Edinburgh Medical Journal*, that this woman was exhibited at a meeting of the Edinburgh Obstetrical Society on the 28th March, 1861, and she then stated that, "since the operation had been performed" (two to three years probably) "she had found herself perfectly well, and was now able to do all her ordinary work as a laundress, for which she had been utterly incapacitated."

M. Gosselin has recorded a case that he had under his care in the Hôpital Beaujon, in which subcutaneous section of the muscles was tried, but, he says, failed. Hesitating to adopt the extreme measure of removal of the coccyx, he again had recourse to palliative treatment, and suggested the simple use of an india-rubber air-cushion. "After the patient had steadily continued this plan for twelve days, she had so far lost her pains as to be discharged from the hospital in a fair way of convalescence, since nature herself, the stress on the parts being taken off, would doubtless complete the cure, under the favourable auspices of rest." M. Gosselin says it was found necessary to regulate the bowels by a rhubarb aperient, to prevent hard motions passing over the tender part.

The Editor of the *Gazette des Hôpitaux* quotes, in connection with this case, a similar one, cured, he says, in a similar way, which fell under his observation some years ago; but it will be observed that in M. Gosselin's case the cure was not by any means complete when she left the hospital, and in the case that has been recently under my care, a long continued and careful trial was made, before the operation, of india-rubber cushions, and other devices for keeping off pressure, without any benefit whatever.

Scanzoni states that leeches to the coccyx, tepid baths, warm fomentations, and, if the pain have a neuralgic character, subcutaneous injections of morphia, have seldom disappointed him in effecting a cure. He never found it necessary to adopt the subcutaneous section. I have already mentioned that in many of his cases the pain appears to me to have been only sympathetic or reflected, and I find that of the twenty-four cases but ten were cured, nine were relieved only, the result in three cases was not known, and in two the evil remained unrelieved by any treatment.

Mr. Bryant has published a case in which he performed the subcutaneous section with perfect success, and Dr. Godfrey, of Sonora, has published a case in the *American*

*Journal of Medical Science*, in which he had operated also with success. The disease had lasted ten years, and the patient stated "that she had consulted a dozen of the best physicians in Tennessee, under whose treatment she successively was for a good while, without deriving any benefit from it, and finally they pronounced her incurable."

I have not been able to find in our systematic treatises or journals, any references to the disease beyond those I have noticed thus briefly, and I believe the disease has not hitherto been described by any of our Irish writers, nor has Simpson's operation for it been performed in Dublin, so far as I can learn, except in the following case, in recording which I beg it will be understood I make no claim as to novelty of observation or peculiarity of treatment.

On the 23rd June, 1866, I attended a young lady in her first labour. She had a very long and an unyielding perineum, and when the head came to press on it, there was very considerable delay, though the uterus acted strongly, and I feared there would be laceration, which, however, did not take place. The case was one in which I might now be inclined to adopt the practice suggested by Dr. Beatty in the paper he read before the Obstetrical Society, on rigid perineum, at the beginning of this Session. Convalescence took place without impediment, but when the lady began to move about, she found she suffered great pain in the coccyx. This pain corresponded exactly to the description given by Sir J. Simpson. It was greatest in sitting down and rising up, and it continued all the time she sat. Walking sometimes pained her, but she had no pain when lying or in defecation.

On several occasions I made most careful examinations of the part and surrounding organs. There was no disease to be detected in the uterus, or its appendages, nor did the rectum present anything abnormal. There was some thickening at the articulation of the coccyx with the sacrum, and pressure here caused great pain, more so than at any other part. I confined this lady to the sofa for some time when she first complained, and gave iodide of potassium, and applied iodine over the part, but though this was continued as long as her general health would permit, she derived no benefit. I then allowed her to sit up and move about a little, making her use an air-cushion, but this gave no relief. She thought a firm cushion of a horse-shoe shape, and stuffed with hair, was better than the air-cushion, but neither this nor the local use of sedatives, nor tonics, and change of air, were of any real service. At length I determined to suggest the subcutaneous section of the muscles, being influenced to do so in a great degree, by hearing from Dr. Beatty, in the course of a conversation on the subject, that all the patients he had met having this disease, had died of phthisis, and I saw that my patient was daily losing strength and flesh from the constant pain she suffered. When I proposed it, she at once consented, and told me then, for the first time, that her mother, though she recovered ultimately, had suffered from the same disease for many years of her life, and was often obliged to kneel at table instead of sitting down.

On the 30th of March last, I proceeded to perform the operation, assisted by Mr. Maurice Collis. Having congenaled the skin over the part with Richardson's apparatus, I introduced a narrow long-bladed tenotome at the point of the coccyx, and passed it on the flat, close to the right side of the bone, to above the part that I had found tender on pressure. I then turned the edge so as to cut from behind forwards, and, keeping close to the bone, divided all the tissues on that side. I now carried it round the apex, cutting all the fibres attached there, and, without taking out the knife, passed it up on the left side, and divided the tissues there in the same way as on the right. Only a few drops of blood escaped through the small aperture in the skin, and I applied a compress and bandage to limit the subcutaneous hæmorrhage, which was, notwithstanding, considerable, and was followed by inflammatory hardness and swelling, so that she could not sit, but even before this was gone, she found, greatly to her delight, that all the old pain had disappeared, and she has remained perfectly

free from it ever since, and has improved in strength and condition. I may mention, as showing her freedom from pain, that on the 16th of May, she drove for five hours on a common outside car through the County Wicklow, without any inconvenience.

*P.S.*—Since this paper was read at the Obstetrical Society, I have received a copy of a most valuable work, by Warren, of Boston, entitled "Surgical Observations, with Cases." The author has devoted a section to injuries of the coccyx, and details six cases illustrative of the severe and long-continued symptoms arising from injury to this bone. Mr. Warren believes these resemble most closely the acute pains which attend periosteal inflammation. "Scarcely an instance," he says, "can be said to have resulted in perfect recovery, and many of them have caused severe local symptoms for some months, and even years, afterwards." In the first case the injury was caused by a fall on the stairs, "the pain and inability to sit lasted more than a year, and the sensitiveness of it continued for ten years after the accident." In the second case, also caused by a fall on the stairs, there was some displacement of the bones, which was adjusted at the time; at the end of six or seven months the patient was able to walk a little about the room with support—"she did not recover from the immediate effects of the accident for one or two years, and now, at the end of eight years, is not able to ascend stairs without suffering." Another of the patients had the coccyx fractured and displaced some years before. "At the time, she was confined about five weeks with very severe symptoms, and never ceased to suffer in the part since." Remarkable on these cases, Mr. Warren says Dr. Simpson has described the affection, "and in some obstinate cases, after having tried all remedies in vain, proposed, and practised with success, the girthing of the coccyx by sub-cutaneous section, just above the diseased part, so as to cut of all nervous communication with it." Mr. Warren does not seem to have performed any operation for the disease himself, and it will be seen from the foregoing he has not correctly apprehended Simpson's operation, or the objects proposed to be attained by it.

#### ON THE PRODUCTION OF ANÆSTHESIA BY THE VAPOUR OF ABSOLUTE ALCOHOL.

By HENRY MAC CORMAC, M.D.

CONSULTING PHYSICIAN TO THE BELFAST HOSPITAL.

THE many deaths which now lie at the door of chloroform, administered as an anæsthetic, loudly proclaim the deep importance of supplementing or even of entirely superseding it, if this be only possible, and otherwise proved to be desirable. It will be admitted, without dissent, that in the cases which suit it, the ether spray will be uniformly preferred. But there are cases which the ether spray does not suit, and in which, if we have no better resort, we must still have recourse to chloroform. But is there no better resort? Is there no other anæsthetic which will better suit the requirements of the case? There are the oxides of carbon. In Paris the protoxide of nitrogen has had its claims recently urged strongly. It is a very agreeable, and it is said to prove a safe anæsthetic. Dr. P. Smith speaks hopefully of the tetra-chloride of carbon. He has also tried it with promising results. Ether has many advocates. It is preferred in Lyons. But it is not exempt from risk; and, perhaps, if it had been resorted to as often as chloroform has been resorted to, it might prove just as fatal. Under these circumstances, I should wish to turn the attention of the Medical Profession to the possible use of the vapour of absolute alcohol. I am not aware that the vapour of alcohol has ever been resorted to as an anæsthetic, and yet, it seems to me to have very many claims to attention. In the first place, people are continually getting drunk, and though drunkenness kill a few, there is, I believe, no other known pathological condition from which so many persons are known to recover.

Alcohol produces its action more slowly than do most other anæsthetics, and therefore, and in so far, so much the

more safely. It will act by inhalation, as well as when taken into the stomach. I have known repeated examples of intoxication produced in spirit stores by the inhalation of the fumes of alcohol, as when men have been engaged in transferring spirituous liquors from one cask to another. I propose, therefore, that the vapour of absolute alcohol, or at least alcohol of a certain strength, should be employed, as chloroform is employed, in order to induce anæsthesia. The trial were easily made, and the results, I would venture to anticipate, would be such as to encourage perseverance. Although one might hardly hope for final results, still, a scientific commission to report on the various possible anæsthetics, after due trial, could not but be productive of advantage. Meanwhile, I should wish here to cite a case of death from chloroform, which does not seem to have come under the notice of English medical men. It is reported in the *Weekly Globe*, Toronto, Upper Canada, 22nd March, 1867:—

"About twelve years ago, a man named John Gould (lately residing in the vicinity of Hamilton) was wounded in the fore and upper portion of the thigh by a jack-knife, which cut the femoral artery, causing much hæmorrhage, but, being of a strong constitution, the loss of blood affected him very slightly. A cure was effected in time, and he appeared to have attained his usual vigour. After the lapse of ten and a-half years, a small swelling appeared directly on the spot where he had been stabbed, which proved to be an aneurism. He was treated by several medical gentlemen in his vicinity, but without success. He came to Toronto, and put himself under the care of Dr. Beaumont, who procured his admission into the General Hospital on the 16th November last. The aneurism was so high up that the artery, instead of being tied, as is usually the case, in the leg, was to have been tied in the lower portion of the abdomen, necessitating a very delicate operation, and one of so much interest that the following gentlemen were present to witness its execution at the Hospital:—Drs. Newcombe, Thorburn, Lizars, Aikins, Wright, Hodder, Philbrick, Williams, King, Riddell, O'Dea, Rosebrugh, Henry Wright, D. D. Wright, Richardson, William Ogden, Winstanley, Constantines, Rowell, Howson, the Military Surgeon of Toronto, Captain Stratford, Alderman Dickey, the House-Surgeon of the Hospital, Dr. Hampton, and others. About two hundred students were also present. About half-past one the patient was brought into the theatre and placed on the table. Previous to operating, the surgeon, Dr. Beaumont, gave a history of the case, stating that the operation was one not always successful, and which few had had the honour to perform—only one similar having taken place in Toronto. Having placed the patient in position, Dr. Henry Wright administered the chloroform. The patient, after inhaling for a short time, appeared to be sinking into a deep sleep, and, beyond a few vigorous struggles, showed no reason why the anæsthetic should be discontinued. Dr. Beaumont got his instruments in readiness, and was about to plunge his knife into the patient when the attention of the attendants was called to the congested state of his lips and face, which were of a purplish hue. Steps were immediately taken to resuscitate the patient—cold water was dashed in his face, ammonia applied to his nostrils, the electric battery to the nerves of the chest and neck, and finally he was rolled on the table after the manner of recovering drowned persons, but with no avail—the spirit had fled."

#### CASE OF RETAINED PLACENTA— HOUR-GLASS CONTRACTION, WITH MORBID ADHESION AND HÆMORRHAGE.

By H. M. JONES, M.D., M.Ch., L.R.C.S.E., Etc.

PHYSICIAN CORK CITY DISPENSARY, DEMONSTRATOR OF ANATOMY, QUEEN'S COLLEGE, CORK.

THE particulars of the following case may interest your readers, presenting to my mind some features that may attract the midwifery practitioner:—

Mrs. A.—n consulted me, about the latter end of October, suffering then from a white discharge from the vagina and os uteri, which, on enquiry, I found succeeded a severe attack of syphilis, from which she was at this time recovering. On examination I detected some slight ulceration on the inside of vagina, and she told me that the husband suffered severely also from venereal disease. They both had undergone medical treatment, lately her catamenia had ceased, when suddenly a flow of blood came on which weakened her greatly for some time. She had not any discharges since this occurrence, about a month previously to consulting me, and suspecting that she might be pregnant, she came to me. The discharge and accompanying symptoms of pain disappeared under a mild mercurial course, local injections, and lotions. Since this she had been going on well, but soon afterwards told me she felt the movements of the child. I saw nothing of her afterwards until the 4th of May, when she called on me and said that she had two days previously again lost a good deal of blood suddenly, since which she had not felt the movements of the child as hitherto. I ordered her a castor oil draught, and enforced perfect quiet. On the 5th I was summoned to see her, and she was complaining of slight labour pains, which had lasted some hours. On making an examination I found the os quite undilated, and learned from her that there had been no discharge since that on the night of the 1st. At 12:30 P.M., the same night, I was again called on, and found my patient's pains had altered to very inefficient, short, but frequent bearing down pains, which having had no effect on the os, and her pulse having risen since my previous visit, I ordered her a mixture containing tartarized antimony and laudanum, the doses of which were to be frequently repeated (*i.e.*, every second hour) during the night. About 5 A.M. I was brought by the husband in a hurry, and when arrived the child (dead) was lying attached to the mother, who immediately after its expulsion had lost a considerable quantity of blood.

The child was quite putrid about the thorax, green and discoloured, being of a dark brownish hue, and mottled elsewhere, and so soft was it, that the nurse who had aided in its extraction, for it had come feet foremost into the world, and very rapidly, told me that she was certain it would have broken across during its exit, which idea on her part, considering its putrescent character, I was not astonished at. The child was delivered about half an hour, so having divided the cord and ligatured it, I turned my attention to the mother, who I found rather weak and very anxious. On placing my hand on the abdomen, I found, as I thought, the uterus pretty well contracted. On questioning the nurse, I discovered that she had endeavoured to remove the placenta, and had passed her hand up, but not being able to stir it by the cord, and not finding it she sent in haste for me. Making the funis a little tense, and using slight traction, I saw that it quickly returned into the vagina, when I allowed it, and that a general oozing of blood occurred immediately I did so. I applied cold to the abdomen outside, using pressure with my hand; having despatched a messenger to my house for some ergot. On again making the cord tense, and using some very slight traction high up on the cord, the feeling was conveyed to my hand, as if the placenta was partly loose, which idea was confirmed by a fresh gush of blood, which came on immediately after a severe labour pain. On consideration, I thought there might become morbid adhesions retaining the placenta, and which, if not detached, dangerous hæmorrhage might ensue. I accordingly proceeded to pass up my hand, guided by the cord, and on getting it inside the os externum, slight hæmorrhage going on at the same time, a severe labour pain came on, which expelled the cord and portion of an extremely rotten and discoloured placenta. There was now no time to lose. The hæmorrhage became profuse, so I passed up my hand, which, though naturally a small one; I found great difficulty in getting through an extremely contracted uterus, of the true hour-glass variety.

My arm, which was first deluged with blood, acted for

the time being as a plug, and partly allayed the hæmorrhage. When I got my hand into the superior cavity, I found high up attached to its summit the placenta, and adherent pretty firmly to the wall of the uterus. By a good deal of trouble, scraping from above down, I detached a loose mass, which I satisfied myself must be the greater portion of it. The difficulty now remained of getting it through the greatly contracted uterus, and by which my arm was firmly caught. However, slowly and with great caution, and, I confess, a certain degree of fear (for I felt the mass crumbling in my fingers), I drew it down, accompanied by a large clot; some slight hæmorrhage ensued, but nothing of any consequence. I was not satisfied with the appearance of the placenta that all had come away, so I again introduced the hand, and succeeded in detaching one or two moderately sized portions. I now gave my patient (as this last operation had rather weakened her, and caused great pain) an ounce of brandy, and, afraid that any might yet remain, I introduced my hand the third time, but could only succeed in bringing away a small bit of a membranous character. Hæmorrhage had now entirely ceased, so I got the binder well on and sent for a medical friend who lived adjacent. In meantime I gave her twenty-five drops of *liq. ergotæ*. On consultation we determined that, as the whole placenta appeared to have been brought away, it was not necessary to proceed further; and the patient, being now free from pain and no blood oozing, expressed a desire for sleep. I having given directions as regards her diet, left, desiring them to continue small doses of the antim. tart. mixture during the day. I found her that evening at six P.M. going on well; no bleeding; pulse 70; had slept well since morning; no headache, complained of slight pain over pubic region; discharge coming from vagina heavy and bloody; next day expressed herself much better; slight pain over pubis still. Ordered *ʒi. ol. ricini*, as bowels confined; discharge of lochia abundant, but foul smelling, and small bits of placenta coming away with it.

Tuesday evening.—Discharge continuing still bloody; pain over uterine region gone; pulse and secretions healthy.

At 12:30 P.M. she complained of intense pain, and appeared to suffer most excruciating torture over the abdomen, which rapidly assumed an alarming character. The lochia towards evening became less. I at once ordered strong turpentine fomentations, which freely reddened her, and three powders containing each:—

*Hydrarg. submur.*, gr. iii.

*P. antim.*, gr. iii.

*Morphiæ acet* gr. ʒ.

*Una secund* ℞ *hora sumend.*

Wednesday.—At 8 A.M., she was nearly free from pain, and about three hours after the stupor passed a decomposing portion of membrane per vagina. I ordered a solution of permanganate of potash (three grains to eight ounces of water), to be injected three times a day into the vagina. This gave her great relief, having the effect of completely removing all fetid odour from the discharge, producing a beneficial and permanent effect; she continued these injections until May 13th; she is now perfectly well and up. The very rapid expulsion of the child, and the fruitless attempts of the nurse to get the placenta away must have induced the peculiar contraction referred to. The difficult question I especially felt in this instance was the propriety of introducing my hand! When, having made tense the funis, I saw the hæmorrhage, the semi-attached feel conveyed to my hand, the discharge of blood, the history of the case, determined me not to wait the usual limited time! for I was convinced that I had to deal with a morbidly adherent placenta partly detached. As one young in midwifery practice I may be excused for bringing these details forward; yet, I trust that those more experienced in such cases will bear this fact in mind while perusing them.

The effect of the permanganate of potash in this instance verifies the reputation it has as a powerful deodorizer and

antiseptic, and I can recommend its use as most beneficial in all similar cases.

## Hospital Reports.

### ST. BARTHOLOMEW'S HOSPITAL.

#### CASES OF STRANGULATED HERNIA, WITH GANGRENE OF THE INTESTINE.

Under the care of Mr. THOMAS SMITH, F.R.C.S.

##### *Femoral Hernia—Strangulation four days.*

*Case 1.*—A male, æt. 45, was admitted into St. Bartholomew's Hospital September 25, 1865, under Mr. T. Smith's care. The patient has had a rupture nine years, has never worn a truss, and no attempt has ever been made to return the bowel, which has all that time been protruded. Symptoms of strangulation have existed four days; there has been no action of the bowels during that time, and vomiting has occurred at frequent intervals during the last three days.

There was a small, tense, and tender swelling in the right groin; the abdomen was slightly tender on pressure; pulse under 80; the warm bath and taxis under chloroform had been employed before his admission, Mr. Smith therefore at once proceeded to operate.

Gimbernat's ligament was divided external to the sac without effect; the sac was therefore opened, and was found to be adherent to the bowel by recently effused lymph.

The small knuckles of intestine within the sac was quite gangrenous.

The intestine being drawn down about an inch, its healthy portion was attached by two silver sutures to the margins of the wound in the skin, and a poultice was applied.

The patient progressed uninterruptedly well after the operation, all his motions passing by the wound; the only difficulty that occurred in the management of the case was that, from the opening in the intestines being high up in the canal the patient suffered somewhat from deficient nourishment. From the first he was fed with one or two nutrient enemata daily in addition to his other food.

Two months after his admission this man was discharged at his own request, a very small opening remaining at the site of the operation; this opening gave him little trouble, and was at the time of his discharge rapidly closing. He wears a truss with an ivory plug.

In this case the ordinary rule of practice in cases of gangrenous intestine was departed from—that is, instead of dividing the stricture, laying open the gangrenous part, and allowing the gut to remain *in situ*, the common plan of procedure, the intestine was pulled down a very short distance, and fastened by suture to the external wound; an additional, and perhaps unnecessary, precaution adopted to prevent the escape of feces into the abdominal cavity. It is worth while observing that this attachment of the bowel to the external wound by sutures did not seem in any way to retard the process of spontaneous cure of the artificial anus—since, at the end of two months, the unnatural orifice had all but closed; indeed, another week's rest in bed would almost certainly have completed the cure.

##### *Inguinal Hernia—Strangulation one week.*

*Case 2.*—March 4th, 1866, a man æt. 65, was admitted under Mr. T. Smith's care, suffering from strangulated inguinal hernia. The hernia has existed for fourteen years, and a truss has generally been worn; symptoms of strangulation have lasted one week, and vomiting for the last six days. The patient being in a state of collapse the operation was at once proceeded with. The sac was opened before any attempt was made to return the bowel. The intestine, just below the external ring, was quite healthy in appearance, and no constriction existed at the ring;

there were no adhesions to the sac or margins of the ring. On turning the intestines out of the tunica vaginalis (the hernia was congenital) about three inches of the lowest part was found to be gangrenous. The healthy portion of the gut was returned, sutures were passed between the bowel and external wound, and the mortified parts were freely laid open. The patient was moribund at the time of the operation, and died four hours afterwards. Apparently the originally strangulated intestine after becoming gangrenous had slipped down into the bottom of the sac, drawing with it a fresh protrusion. The relaxation of the stricture might have taken place in consequence of the occurrence of gangrene in the bowel, and coincidentally with the symptoms of general constitutional depression.

##### *Inguinal Hernia—Strangulation three days.*

*Case 3.*—A man aged 60, was admitted into St. Bartholomew's Hospital December 18, 1866, under Mr. T. Smith's care. The patient was apparently deranged in his mind, and was reported to have been in this condition for two years. He had had a rupture for some years, and had never worn a truss. The hernia was generally down, but was reducible at will. The bowels had not been moved for three days before admission, and during the last forty-eight hours vomiting had been frequent.

There was a large scrotal hernia, very tense and tender to the touch; the integuments over the lower part of the swelling were oedematous; about the neck of the hernia there appeared to be but little constriction. Taxis in the warm bath and under chloroform failing to give any relief, an operation was performed.

The external abdominal ring was examined, and from its lax condition it was evident that the obstacle to the return of the intestine lay elsewhere. The sac was then opened at its neck, and the contained intestine was found in a natural state. By tracing the intestine downwards into the scrotum the very narrow and thickened neck of an old sac was reached, within which was enclosed a considerable quantity of the small intestines, fully four inches of which was completely gangrenous. The neck of this sac was freely divided, and it then became apparent that the hernia was congenital. The intestine was returned, except the portion that was gangrenous; it was attached by silver sutures to the margin of the wound, and the mortified part was freely laid open. Next day the pulse was 84; the tongue was clean and moist; skin cool. There was a free escape of feces from the wound, and in every respect the patient was doing well. From the character of the discharge from the bowels it was evident that small intestines had been laid open high up. It was found necessary to thicken all food with arrowroot to delay somewhat its escape from the artificial anus. Nutrient enemata were administered twice daily.

The patient, except for an attack of bronchitis on the third day, went on uninterruptedly well, and at the end of a week the gangrenous portion of the intestines had separated, and the wound was granulating. A day or two later the patient began to shew signs of severe constitutional disturbance, and an abscess began to form in the right iliac fossa, with a tendency to spread upwards and outwards beneath the abdominal muscles. This was opened, and a large quantity of pus, mixed with air, escaped. Three days afterwards the patient died from exhaustion.

In this case the old hernia sac had been displaced, and thrust downwards into the scrotum by a recent protrusion of intestine—a condition which rendered it almost impossible to reduce the protrusion by simple taxis, since, in the taxis, the surgeon's efforts are directed to return the bowel through the abdominal ring, whereas, in this variety of hernia, the constriction lies low down in the scrotum, at the neck of the displaced sac.

##### *Femoral Hernia—Strangulation seven days.*

*Case 4.*—A woman, æt. 50, was admitted into St. Bartholomew's Hospital, Feb. 9, 1867, under Mr. T. Smith's care.

She had suffered from hernia for many years, and had never worn a truss; the hernia was generally reducible. It has now been irreducible for a week, and during the whole of this time she has suffered from constipation, and from vomiting at intervals. She has had no medical advice but has taken, during the week, three doses of castor oil without any effect on her bowels.

She looks very exhausted, and complains of feeling faint; tongue dry and brown; pulse very feeble and frequent. The belly is soft and not tender on pressure; there is almost constant vomiting. In the left groin is a small femoral hernia, slightly tender on pressure, and not at all tense.

The ordinary operation was performed under chloroform. The sac was opened; it contained a small knuckle of intestine, showing but little signs of vascular congestion, but being apparently tightly constructed at the femoral ring. The stricture was divided, and the intestine returned, and attention was turned to a small piece of omentum, which was protruded with the hernia, and was adherent to the outer margin of the femoral ring. This being cut off, it was observed that fecal matter was welling up from the wound in large quantities. The intestine was, therefore, again drawn down through the ring, and examined. A ragged, ulcerated opening, the size of a sixpence, was found in the bowel, just at the neck of the protrusion, and opposite to Gimbernat's ligament. The bowel was drawn further down, and was attached to the margins of the wound. The patient died four hours afterwards with all the signs of acute peritonitis, and after death feces were found in the peritoneal cavity.

It is more than probable that, in the foregoing case, the sloughing of an isolated patch of the intestine, opposite the seat of stricture, had relieved the severity of the stricture, and had allowed the protruded part to recover itself. This would account for the healthy appearance of that part of the bowel seen on opening the sac. The ulcerated opening in the bowel must have been adherent to the inner margin of the femoral ring, since no escape of feces occurred until the bowel was detached from its connections by being returned into the abdominal cavity. The more prudent course would have been to have first drawn down the bowel, after dividing the stricture, to see if it were in a fit state to be returned into the peritoneal cavity. Mr. Smith was deceived by the healthy appearance of that part of the bowel that came into view on opening the sac; and thus he omitted to inspect the condition of the intestine where it was girt by the margin of Gimbernat's ligament.

#### ON DISEASES OF JOINTS.

By **HOLMES COOTE.**

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

THE Annual Statistical Reports published by the authorities of St. Bartholomew's Hospital, afford many subjects for interesting inquiry and reflection. No subject, perhaps, is of greater importance than that of disease involving the articulations. The number of cases admitted is always large. During the past year there have been 60 cases of *synovitis*, and no deaths; and 78 cases of *diseased joints*, with a death-rate of 6.41; the total of all cases under treatment being 138.

The knee-joint has been excised six times—three patients between the ages of 5 and 10, the other three between the ages of 10 and 20. Of these, three died—the first, aged 5, of pyæmia, on the 18th day; the second, aged 20-30, of pyæmia, on the 22nd day; the third is reported in one column "unrelieved," and in another is included among the fatal cases—the result, as far as I am concerned, being the same.

In remarking on this very unfavourable aspect of the operation of resection of the knee-joint, I would observe that in all cases it was performed at an age most favourable for convalescence and recovery—namely, between infancy and early adult life.

It cannot be said that diseases of joints are commonly fatal; on the contrary, the death-rate is very low. Nor can it be urged that amputations are commonly necessary. During the past year, there has been no amputations at the hip-joint. There have been four amputations of the thigh for disease of all kinds in males, one in females, making a total of five; of these, one male, an adult, died of diffuse cellulitis. The leg was amputated on three occasions. Of these cases, two died. The ankle and foot, each once; recovery in both instances. No amputation was performed in the upper extremity during the same period.

Much of this favourable return is due to the great degree of patience in carrying out surgical treatment; to a greater command of valuable surgical appliances and apparatus, and to the yearly increasing improvements in ventilation, in diet, and in general domestic arrangement, for which this hospital is celebrated.

#### MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

#### SURGICAL RECORDS.

By **WILLIAM STOKES, Jun.**

SURGEON TO THE HOSPITAL, LECTURER ON SURGERY, CARMICHAEL SCHOOL.

STRUMOUS DISEASE OF THE ANKLE-JOINT OF EIGHT YEARS STANDING—EXCISION OF THE ANKLE-JOINT.—AFTER TREATMENT BY THE CONTINUAL BATH—CASE PROGRESSING FAVOURABLY.

IN the domain of operative surgery there are few procedures which have so many warm supporters, or such bitter adversaries as resections of the larger joints. This difference of opinion among surgeons in regard to the value of these operations is due to many circumstances, among which may be mentioned the frequent occurrence of unsatisfactory results, and the unlimited faith which so many surgeons have in the value of rest in the treatment of all forms of articular disease. No one could be more convinced of the value of rest than I am, but I cannot but think, that the surgeon who relies solely on this in the treatment of many forms of articular disease, rejecting all idea of operative interference until the vital powers of the patient become so seriously impaired as to render success in operating highly problematical, fails in duty to his patient and to the cause of true conservative surgery. It is, doubtless, this tendency among surgeons to make operative interference the *dernier ressort*, that has been so often the cause of want of success in these procedures, and brought them consequently into an ill-deserved disrepute.

To the excision of the ankle-joint a special class of objections have been urged, based, first, on the mechanical difficulty of the operation, and, secondly, on the difficulty, and according to some, on the impossibility of determining, even approximatively, the amount of disease that may have to be removed. With regard to the first of these, it is unnecessary to dwell, for no mechanical difficulty should ever deter the surgeon from performing an operation that may be of ultimate advantage to the patient, and with regard to the second, it appears to me, that the best answer to give is that if the amount of disease be found so extensive as not to justify resection, there is then nothing to deter the surgeon from amputating at the ankle-joint, after the manner recommended by Professor Syme or Pirogoff.

In the present communication, I shall not enter into any of the historical details of this procedure, but proceed at once to relate with all possible brevity, the leading particulars of the case in which the operation was performed for the first time in Ireland.

J. M'Graith, æt. 27, a boot-maker by trade, was admitted into the Meath Hospital, under my care, on the 10th of last April. He stated that about eight years previously he received the kick of a horse over the inner malleolus. The joint swelled after this, and was extremely painful. This seems to have subsided under suitable anti-phlogistic measures. The swelling, however, never entirely

disappeared. After some time abscesses and sinuses formed, which never healed, and from which purulent matter, varying as well in consistence, as in quantity, continually oozed up to the time of his admission into hospital. In other respects, the patient was in good health, though, as might be expected, much debilitated by the long confinement and the continuous discharge from the sinuses. On probing these, I found that the direction of all was towards the astragalus, a circumstance which went far in making me come to the conclusion that the disease was probably limited in extent, and possibly localised in the astragalus and articulating surface of the tibia. Having formed this opinion, I deemed the case a fitting one for excision, and I proposed it to the patient, who gladly acceded, and, my colleagues concurring in the propriety of the operation, I performed it on the morning of the 29th of April, in the following manner:—

A long vertical incision was made along the posterior edge of the fibula, and then brought obliquely forwards and inwards towards the internal cuneiform bone. A somewhat triangular-shaped flap was then dissected backwards, a step in the operation which was attended with much difficulty, owing to great matting and thickening of the soft parts. This having been done, the next step was to excise the end of the fibula. This was effected with great difficulty, owing to the fibula being firmly ankylosed below with the tibia. The outer portion of the extremity of the fibula was found softened and diseased. A chain saw was then passed round the fibula about two inches and a-half above its extremity, and divided. Owing, however, to the firm ankylosis below, it could not be removed until a section was made separating it from the tibia by one of Langenbeck's small resection saws. This having been done, the excised portion of the fibula, with a small portion of the outer edge of the tibia, to which it was attached, was easily removed. It then was obvious that not only the extremity of the tibia, but also the astragalus, were extensively diseased. The greater portion of the latter was removed, chiefly by the straight and rectangular gouges. As we saw then that the inner malleolus was extensively engaged, we deemed it advisable to attempt the dislocation of the tibia outwards through the wound. Mr. Porter, whose assistance at this and every stage of the operation was invaluable, made the attempt to dislocate the extremity of the tibia through the wound. It was found impossible. More of the diseased structures were then removed, sometimes by the gouges, Langenbeck's and Hey's resection saws, and also by an ingeniously-constructed American forceps, of great power, which was kindly lent to me by my friend Dr. E. O'Grady. A second, and then a third attempt was made, to bring the extremity of the tibia through the wound. The last attempt proved successful, and our efforts were well rewarded, for it was plain that had we trusted to the instruments we had previously been using, we never could have removed all the disease we found situated in and about the inner malleolus. There was no necessity found for removing the periosteum by any of the raspatoria for the purpose, for it was found detached and thickened, lying loosely on the surface of the bone. A slice of the tibia, about a quarter of an inch in thickness, was then removed by an ordinary amputation saw, and the resection was then complete. One vessel only had to be secured, which I did by acupressure, adopting the method of "half rotation," or first variety of the fifth or Aberdeen method. Nothing could have been more entirely satisfactory than the way the hæmorrhage was arrested by this procedure. A piece of dry lint was then placed in the wound, and the edges brought together by five or six points of silver wire suture. A gypsom bandage was then applied from the toes to the junction of the upper with the middle third of the leg, in the manner I have already described, in the *Dublin Quarterly Journal* for May, 1865, the particulars of which I need not therefore now enter into. The patient was then placed in bed with the limb slightly elevated, and ordered forty drops of Battley's sedative, in a little sherry.

8 P.M.—Pulse 136; suffered from considerable abdominal pain during the day; no sleep as yet; no pain in ankle. Ordered a draught with sol. mur. morphiæ, gtt. xxxv., in an ounce of cinnamon water.

April 30, second day, 10 A.M.—Had a restless night; pulse 140; had several attacks of retching during the night; ordered iced beef-tea and champagne to be taken in small quantities every second hour; also, the following draught to be taken at once:—

℞ Liq. mur. morphiæ, gtt. xxxv.  
Spt. chloroformi.  
Tinct. cort. aurant., aa ℥ss.  
Aque lauro cerasi, gtt. x.  
Aque, ℥vii.  
Fiat haustus. ss.

4 P.M.—Found the patient much quieter, but pulse is still 140. I cut a large oval shaped window in the gypsom bandage over the situation of the wound, and then applied, with a large camel's hair brush over the bandage, a solution of Danmar resin in sulphuric ether, to prevent the action of the water in the continual bath from softening the gypsom. The limb was then placed in the bath, being supported in it by a coarse net. This gave the patient great relief, the pulse fell almost instantaneously to 120.

May 1, 9 A.M.—Had a quiet night; pulse 120, full and strong; no pain in ankle; had several hours sleep.

3.—Pulse 100; skin cool; tongue moist. Free suppuration from the wound; appetite good.

On May 14, I took the limb out of the bath, removed the gypsom bandage, and placed the limb in a box splint. The wound was then dressed with Dr. Richardson's styptic colloid, which I continued to use for upwards of a fortnight. I have had much reason to be satisfied with it, not only in this but in some other cases in which I have employed it. On May 29, the wound being nearly healed, I took the limb out of the box, since which date the case has gone on steadily improving. The only *contre temps* of late has been the formation of some small abscesses in the vicinity of the wound, the discharge, however, from them is steadily diminishing, and I have every reason to believe that the case will be brought to a successful termination.

I shall not, on the present occasion, discuss the various modes which have been suggested and practised by surgeons for performing the operation of excision of the ankle-joint. The method which I adopted differs from those recommended originally by Moreau, and subsequently by Professors Hancock, Langenbeck, and others.

In the operation, as I performed it, there is only necessity for a single external incision. The advantages of this are, in the first place, that the suppurating surfaces are necessarily less in extent, and consequently the chances of rapidity of healing are increased. In the next place, the operator avoids injuring the extensor tendons of the foot. Thirdly, any injury to the tendon of the tibialis portions is avoided; and lastly, no risk whatever is run of wounding either the anterior or posterior tibial arteries.

With regard to periosteal preservation, as I have frequently directed attention to the importance of preserving with all care that membrane, in the great majority of operations that have for their object the removal of diseased bone, I shall not, on the present occasion, dwell on this important modification of excision of the ankle-joint, as first practised for the removal of diseased bone by the elder Moreau, in the year 1791.

---

CONVALESCENT HOSPITAL.—The Liverpool Committee for obtaining subscriptions for the relief of the sufferers by the cotton famine, finding they have a balance in hand of £40,679, 5s. 1d., propose to devote this sum to the building of a Convalescent Hospital, in a healthy position near the town, to act as a supplement to the existing infirmaries and hospitals. The proposal has met with general approval, and a committee has been appointed to carry it out, consisting of, amongst others, the chairman and treasurer of each of the principal Hospitals in Liverpool.

## Summary of Science, &c.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.O.S.L., F.R.G.S.I., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

### CANTHARIDIN.

PROF. DRAGENDORFF states that he has found the cantharides fly to contain a volatile body which acts on the organism in a similar manner to cantharidin. Freshly-powdered cantharides are moistened with water and distilled. The portion going over, below, and at 100° C., and which has an acid reaction, contains the new body. We are of opinion that Prof. Dragendorff's substance is simply cantharidin carried over in some volatile product in which it is soluble. The quantity of cantharidin that will act as a vesicant is very minute, and is easily distilled in the presence of many fluids (e.g. acetic acid).

### ON THE MINERAL ELEMENTS OF CANTHARIDES.

Cantharides containing 8.18 per cent. of moisture give 5.79 per cent. of ash. Exhausted by boiling water, they left a residue which amounted to 68.29 per cent., which gives 1.62 per cent. of ash.

The aqueous decoction treated by its weight of alcohol gives a residue reaching 3.90 for 100 of ash.

The filtered liquor gives 19.63 per cent. of solid substance, and 2.71 per cent. of ash.

The following table represents the analyses of the ashes :

	Ash insoluble in Water.	Ash soluble in Water and Alcohol.	Ash soluble in Water.
Lime	... 0.436	0.311	0.340
Magnesia	... 0.125	0.237	0.191
Potash	... 0.048	0.675	0.136
Soda	... —	0.122	0.040
Phosphoric Acid	... 0.303	1.237	0.577
Sulphuric Acid	... 0.0528	0.004	—
Carbonic Acid	... 0.030	—	—
Silicic Acid	... 0.600	0.027	—
Chlorine	... —	0.03	—

—M. Kubly (*Journal de Pharmacie et de Chimie*), April, 1867.

### CEMENT THAT WILL RESIST FIRE AND WATER.

We have no doubt that the following receipt, which appeared in *Cosmos*, 8 Mai, will be found useful, particularly in large laboratories, where good cements are invaluable. Dr. Junemann uses the following mixture. "It will be found very useful, particularly in the distillation of fatty matters, and volatile oils, for soap makers' boilers, air pumps, and all kinds of steam or vapour joints."

He takes two parts of iron filings, quite free from oxide, and passes it through a fine sieve. He mixes this with one part of potters' clay, which must be perfectly dry and finely powdered. The whole is then worked up with strong vinegar, until it is quite plastic. The cement must be used at once, as it hardens rapidly.

### CARMINIC ACID.

H. Hlasivetz and A. Grabowski, state that when Carmine is boiled with diluted sulphuric acid, it splits into carmine red, and sugar. The latter reduces Trommer's solution, and gives Pettenkofer's reaction, but neither ferments or acts on polarized light; Traces of it are dissolved by alcohol. Dried at 50° its formula is C<sup>6</sup> H<sup>10</sup> O<sup>5</sup> at 100°, C<sup>6</sup> H<sup>8</sup> O<sup>4</sup>.

Carmine red, C<sup>11</sup> H<sup>12</sup> O<sup>7</sup>, is a dark purple amorphous substance, reflecting green light, soluble in water and alcohol, with a fine red colour, and insoluble in ether. Fused with a potash solution of appropriate strength, carmine red gives oxalic and succinic acids, and coccinin, probably C<sup>14</sup> H<sup>12</sup> O<sup>5</sup>—a body resembling chinon. Its crystals polarise light, are insoluble in water, easily soluble in alcohol, difficulty

so in ether. Coccinin dissolves very easily in dilute alkaline solutions, and in such solution is one of the most sensitive bodies to the action of oxygen. The solution is at first yellow, then violet, finally, a magnificent purple red. Few bodies give rise to so many phenomena of colour as coccinin. From the splitting of carminic acid into carmine red and sugar, perhaps Schutzenberger's is the nearest to the real formula of that much investigated body, viz., C<sup>17</sup> H<sup>18</sup> O<sup>19</sup>.

### IODIDE OF SILVER.

From the French of H. Deville.

Hydriodic acid, especially when concentrated and slightly warmed, dissolves silver rapidly with evolution of hydrogen, forming crystallizable hydro-argentic iodide Ag. I, H, I, and on placing the solution of this acid salt, in contact with silver-foil, or on leaving it exposed to the air, whereby the hydriodic acid is gradually oxidised, argentic iodide (Ag. I.), is easily obtained in large beautiful crystals, having the same form as the native iodide, viz., according to Des. Cloizeau, a regular hexagonal prism, with six-sided summits, cleaving very distinctly parallel to the base. Argentic iodide may also be produced by pouring strong hydriodic acid upon chloride of silver, which is immediately decomposed with a hissing noise, like that produced in the slaking of lime. The iodide of silver thus obtained may be dissolved in an excess of hydriodic acid, and converted into the crystallised salt as before.

### NICOTINE.

Dr. C. Huber, says that when treated with chromic acid nicotine gives an acid C<sup>6</sup> H<sup>5</sup> NO<sup>2</sup> yielding easily crystallisable salts and azo compounds. Distillation with lime produces C<sup>5</sup> H<sup>5</sup> N., an oily base soluble in water. The first reaction also produces another acid richer in carbon, and at least one base.

The Journal of the Chemical Society contains an important communication from Dr. Stenhouse, on some varieties of *Orchella Weed*. The same number contains "Graham on the Absorption and Dialytic Separation of Gases by Colloid Septa," which, however, originally appeared in the "Transactions of the Royal Society."

"Proceedings of the Royal Society" contain the following papers, which will be found to possess more than ordinary interest :

*Researches on Gun Cotton.* F. Abel.

*Observations of Temperature during two Eclipses of the Sun (in 1858 and 1867).* By John Phillips, M.A., &c.

*A New Fact relating to Binocular Vision.* By A. Claudet.

Mr. H. Sorby communicates a paper on a *Definite Method of Qualitative Analysis of Animal and Vegetable Colouring Matters by means of the Spectrum Microscope.*

The author describes his apparatus, which is now well known. It is made so that it can be attached to an ordinary binocular microscope with an inch object glass. The scale of measurement is taken from an interference-spectrum produced by two small Nicol's prisms and an intermediate plate of quartz. This produces twelve bands, which gradually increase towards the blue or more refrangible end of the spectrum. The author then proceeds to describe a system of notation in which the common types are used. As this spectral shorthand is not likely to come into use, it is not necessary to enter into its details. Mr. Sorby has endeavoured to institute a regular system of analysis applicable to those substances which give absorption-spectra. This is regularly worked out by the action of re-agents and solvents, and will be read with great interest by those engaged in spectral investigations.

Dr. Maxwell Simpson informs us that he has succeeded in forming *Di-iodacetone*. This substance is the iodine compound corresponding to a body discovered many years ago by Sir Robert Kane, and called by him mesitchloral. It is more generally known as di-chloracetone.

"The Laboratory" for 18th May contains an elaborate

paper on *The Higher Homologues of Chinoline*, by C. Grenville Williams.

F. Wöhler contributes a note to the *Chemical News* (May 24), on the *Direct Estimation of Boracic Acid*.

Pharmacologists interested in *aloes* will find a well-written monograph upon that drug, and its varieties. The author is M. Marais (*Vide Journal de Pharmacie et de Chimie. Mai*).

#### CULTIVATION OF JALAP.

Mr. Daniel Hanbury is of opinion that jalap-root could be cultivated to advantage in Cornwall, Devonshire, and the Isle of Wight, and that it will thrive as a garden-plant during the whole year. In Madeira it would probably also succeed, if planted in situations sufficiently elevated.

#### THE FUNCTION OF BARREN STAMENS.

The use of the long staminodes, as found in *Dombeya angulata*, says Dr. Maxwell Masters, is to convey pollen from the short fertile stamens to the stigma, which, but for their intervention, could not be influenced by it. It is probable that barren stamens in similar cases play a similar rôle.

#### PHARMACY.

##### ADULTERATIONS IN THE DRUG TRADE.

*Bael*.—Professor Bentley notices, in the last number of the *Pharmaceutical Journal*, the substitution of mangosteen (*Garcinia mangostana*) for *Bael* (*Egle marmelos*). The mangosteen rind may be distinguished by its much greater thickness, darker colour, the entire absence of adhering pulp, and seeds, and in the presence of some of the pieces of projecting, radiating, dark-coloured, "wedge-shaped stigmas."

*Hydrargyrum ammoniatum* B. P. has been found to be adulterated with white lead, chalk, carbonate of baryta, &c. One sample consisted of 89.18 per cent. of white lead, and 10.82 of corrosive sublimate.

*Sp. Ether nitrosi* was largely adulterated with water.

##### OXYGEN EMPLOYED THERAPEUTICALLY.

M. Limosin, pharmacien, writes to the following effect, in a memoir which he publishes in the *Journal de Pharmacie* (Mai). The author determined the relative quantity of carbonic acid extracted during the respiration of atmospheric air, and the inhalation of oxygen. A glass balloon was used, holding twenty litres of atmospheric air; the contents of this were inhaled, and each expiration was passed through a solution of caustic baryta, and by this method the amount of carbonic acid exhaled was weighed as carbonate of barium. Twenty litres (about four and a-half gallons) of air gave 2.58 grammes of carbonate of barium.

Twenty litres of oxygen respired gave six grammes of carbonate of barium under similar circumstances—or double the quantity.

From his experiments, it appears to the author that the following conclusions may be allowed—that the quantity of carbonic acid produced during the inhalation of a limited dose of pure oxygen is not such as to threaten too energetic an action, but which, however, is sufficient to produce a marked therapeutic effect.

In his researches "on the oxidation of blood," M. Claud Bernard has shown that the blood of animals whilst fasting absorbs more oxygen than during the time of digestion. It is fair, then, to draw this conclusion—that oxygen, to act properly, should be administered whilst fasting. The property which it possesses of exciting the appetite—which property has been noticed by Dr. Demarquay, and confirmed by a great number of physicians, justifies this method of administration.

The learned physiologist of the French college attributes the greatest resistance to the absorption of oxygen during the act of digestion, to the superabundant quantity of sugar thrown out at this moment by the force of the circulating torrent. At the same he states that certain agents,

on the contrary, increase and facilitate this oxidation. Alkaline substances (chloride of sodium for example) act in this sense.

##### ON THE SEPARATION OF THE OPIUM ALKALOIDS.

M. Kulby, says the *Chemical News*, recommends the following process:—The substance to be examined is extracted with benzol, narcotine, papaverine, thebaine, and codeine, are dissolved. Amylic alcohol dissolves morphine from the residue, and alcohol will extract narceine, if present, in what is left undissolved by the two former solvents.

To separate the four alkaloids, soluble in benzol, cold amylic alcohol is used, which dissolves codeine; very diluted acetic acid will then extract papaverine and thebaine from the narcotine which remains. Finally, thebaine is precipitated from the sulphuric acid solution of papaverine and thebaine, by iodide of bismuth dissolved in iodide of potassium, papaverine remaining in solution.

The *Moniteur Universel* of the 18th January, publishes a decree which divides manufactories into three classes. This decree is published in connection with a report presented to the Emperor of the French, by M. Behic, Minister of Agriculture, of Commerce, and of Public works:—

"La division en trois classes des établissements réputés insalubres, dangereux ou incommodes aura lieu conformément au tableau annéxe au présent décret. Elle servira de règle toutes les fois qu'il sera question de prononcer sur les demandes en formation de ces établissements."—Palais des Tuileries, 31st Dec., 1866.

As this article states, the list is divided into three classes, which three classes include almost every conceivable chemical manufactory, either from their supposed deleterious nature, or from the combustibility of the products used. We may even go further, and state that every industrial pursuit is included in the three classes, many of the substances appear in two, or all the three divisions, e.g.:

"*Première Classe*.—Oxalic acid (making of the) by nitric acid, without the destruction of the noxious gas vapour.

"*Seconde Classe*.—Oxalic acid (making of the) by sawdust and potash vapour.

"*Troisième Classe*.—Oxalic acid (making of the) by nitric acid, with destruction of the noxious gas—accidental vapour."

Thus we are to infer that preference is given to the nitric acid process (although that is the most dangerous), providing that due precautions are taken to prevent the escape of the gas. The list is very long. The above is only given as a specimen.

## Reviews.

IRELAND BEFORE THE UNION. With Revelations from the Unpublished Diary of Lord Clonmel. A Sequel to the "Sham Squire." By W. J. FITZPATRICK, J.P. Dublin: W. B. Kelly. 8vo., pp. 244.

MR. FITZPATRICK'S literary researches into the history of the latter part of the last, and the earlier portion of the present centuries, have thrown upon the occurrences of that, for Ireland, most eventful period, a light under which its condition at the time does not appear from a very creditable point of view. Unfortunately Mr. Fitzpatrick is too searching in his enquiries, and too explicit in his authorities to leave any room for escape from the unpleasant conviction that the Government of Ireland before the Union was corrupt and foul to an extent which would be hardly credited in these days of gushing philanthropy and political vestalism. This last effort of Mr. Fitzpatrick is not below any of his previous works in interest, and we anticipate for it a success commensurate with that of the "Sham Squire," the reading of which has made the buying of this work an absolute necessity. It is not within our province to enter on the general subject matter of the book, and if we have a sentiment on its contents, it is to congratulate our readers on having left the enjoyment of the half-century chronicled by Mr. Fitzpatrick to their grandfathers.

If the rebels were only a tenth-part as great scoundrels as a few of the royalists seem to have been, Ireland must have been simply a social and political pandemonium. Our Profession is represented in Mr. Fitzpatrick's pages by Dr. Christopher Teeling, the physician who attended the Sham Squire, and is named executor under his will. Respecting him the author says:—

"Old physicians describe Dr. Teeling as a man who although he never attained a high rank in his profession, was much respected for his worth and honourable feeling. It was, no doubt, in this conviction that the Sham Squire appointed him his executor; and, perhaps, we find in the character of Teeling thus given the reason why he declined to act. Dr. Teeling lived in Exchequer-street; he is described as a gouty old gentleman, with a strong determination of blood to the nose, indicative of indulgence in convivial pleasure.

"This tradition is confirmed by a verse from one of Dr. Brennan's poetic reviews of the Dublin Doctors, printed in the rare *Milesian Magazine* for July, 1812, which fell under our notice while correcting the proofs of the present page.

"T. was T—g now careless how this world goes,  
Whose fancy had fire that is now in his nose,  
Who floats on the great sea of physic a log  
Deep sunk by its storage of port and of grog,  
When a boy well employed at the mortar and pestal,  
When a man hired to doctor the Sham and his vestal,  
Pretending to honour and duty and high sense,  
Yet plumed in the feather swore against license."

In the "Sham Squire," Mr. Fitzpatrick records that Mr. Dease, the well-known surgeon, being suspected, with good reason, of treasonous complicity, committed suicide to avoid disgrace and punishment. To this statement, Dr. McKeever, in a letter to the author, takes exception, replies:—

"You mention that Mr. Dease was implicated in the abortive political movement of the day, but lacking the moral energy of his friend and associate, Lawless, who succeeded in escaping he retired to his study on hearing that a warrant was out for his arrest, and like Cato, died by his own hand. Now for a plain unvarnished statement of facts. Mr. Dease was one of the medical attendants on the Westmoreland Lock Hospital, and while paying his usual round of morning visits, his attention was directed by the resident apothecary to a man (at that period both sexes were admitted) with a considerable swelling in the groin. Mr. Dease having unfortunately for himself, as well as society at large, taken a hurried superficial view of the case, conceiving it to be one of ordinary abscess, dipped a lancet into it. A torrent of bright arterial blood gushed forth, and in a few moments life was extinct. Instead of an ordinary abscess, it proved to be an aneurism of the great femoral trunk that supplies the lower extremity. Poor Dease, humbled and confused at the egregious error he had so inadvertently committed, retired with an agonized lacerated heart to his study, and, as you correctly state, committed suicide."

In the absence of any proof, we may say that Mr. Fitzpatrick's story is that traditionally current, and has more of the blush of truth than the other version.

To all Irishmen, and to many others who are interested in "the Irish question," and in knowing whether any good reason has existed for the chronic disaffection of England's sister, the book is full of interest, and will be widely read.

**THE SPAS OF BELGIUM, GERMANY, SWITZERLAND, FRANCE, AND ITALY:** a Handbook of the Principal Watering Places on the Continent. Descriptive of their Nature and Uses in the Treatment of Chronic Diseases, especially Gout, Rheumatism, and Dyspepsia; with Notices of Spa Life and Incidents in Travel. By THOMAS MORE MADDEN, M.R.I.A., Licentiate of the King and Queen's College of Physicians in Ireland, &c. London. 8vo. 1867.

DR. MADDEN is so well-known to our readers that we need do little more than introduce this, his latest work, to their notice; observing that, notwithstanding a few defects, it is a most readable book, and will most certainly maintain the high reputation which he has already acquired in putting forth works suited not merely for his own professional brethren, but also for the study of educated men generally. The plan of the work before us may be best understood in Dr. Madden's own words, as expressed in the following extract from the preface:—

"With regard to the plan of this work, I need hardly say

much. In the first place I have endeavoured to lay before my readers a succinct view of the nature and uses of mineral and thermal waters. I have next described the various forms of disease that may be treated by this remedy, and pointed out the mineral water adapted to each particular case.

"In the second part, I have given a detailed account of the principal watering places of Europe, from my personal observations and notes, taken at each Spa. In doing this, I have sought to combine all the medical information essential for the prescribing physician, with those local particulars necessary to the invalid traveller.

"For the narrative and descriptive portion of this work, by which I have attempted to extend its interest beyond the class who would peruse a purely professional essay, I think no apology is necessary. But if it were, I might cite the example of other writers on mineral waters. Moreover, I can see no reason for the opinion of those who think that a medical writer, as such, is precluded from making those general observations which his acquaintance with human nature under various phases, his education, and those opportunities which his profession often give him of studying men and manners more intimately than other travellers, afford."

The body of the work consists of pp. 369, and contains 25 chapters, besides an introduction of 29 pages "On the Nature and Uses of Mineral and Thermal Waters." Chapter I. is on "Dyspepsia and the Spas," and chapter II. dilates "On Gout and its Treatment by Mineral Waters." We particularly recommend the perusal of the introduction, and of these two chapters. But, as the merit or demerit of a book of this kind lies largely in its style and composition, we shall give specimens from chapter XIX, commencing on page 258:

"The situation of Baden is exquisite; the town is accessible; the hotels and lodging-houses are commodious; the people are civil; the shops are good; the cursaal is the richest, and the mineral waters are the poorest on the Rhine. No watering place shows such evidence of prosperity; and none deserves it less. New streets and houses are rising on every side; the number of visitors is increasing each season; the mineral springs are recommended in almost every class of chronic disease, and are suited for hardly any."

"The great rendezvous of all the strangers in Baden is the cursaal or "Conversation-Haus," as it is called, on the *lucus a non lucendo* principle, since conversation is the last thing thought of in these saloons, where the hushed silence which generally reigns paramount, is broken only by the voice of the croupier as he announces the winning colour, or the click of the ball as it spins round the revolving disc. This cursaal always seemed to me by far the worst of the German gambling houses; there is no pretext of any other object—no reading or billiard rooms, as at Homburg or Wiesbaden. In other Spas where gambling exists, it is bad enough, Heaven knows, but still it may be avoided, and invalids may, and do reside for the season without being brought into contact with the gaming table. But in Baden, gambling is the main characteristic of the place; it is thrust before one prominently at every moment, and it would be impossible to escape its atmosphere in the town; everyone speaks of it, everyone thinks of it, and not a few dream of it. As long as the rooms are open, from eleven in the morning till midnight, they are constantly crowded with players, and from morning till night an equal throng press about the tables in the vain pursuit of easy wealth—like moths round a flame, although their wings be often singed, yet the fascination is irresistible, and they still rush back to the danger, until, their golden pinions destroyed, they fall into and perish in the fire they have worshipped."

"The Baden Spa is still prescribed by many physicians, and employed by some patients; but out of the fifty thousand visitors whose names figure in the *Kur-liste*, comparatively few use the waters, either internally or externally. Every morning during my residence there, I visited the various springs and the old and new trinkhalls, and seldom met many valetudinarians at the sources. Occasionally, however, I saw a thin muster of invalids at the Ursprung, and always found some thirty or forty water bibbers in the new trinkhalle. Hardly any of the latter, however, had the aspect of sick people, and several of the gentlemen qualified the dose with some drops of a preparation, more potent than Ursprung water, which the very attractive feminine chemist behind the marble counter dispensed from a black bottle."

In conclusion, we cordially recommend this book not only to our own Profession, but to educated persons of every calling. If

only a very small part of the time spent on reading the iniquitous trash called "Sensation Novels" were used in obtaining the entertaining and important information supplied by books such as this before us, not only would it prove good for maintaining the *mens sana in corpore sano*, but it would also directly encourage literature of a most useful, but, unfortunately, not most popular kind.

### THE GENERAL MEDICAL COUNCIL.

#### A RETROSPECT.—II.

THE motion of Dr. ANDREW WOOD for a Committee "to report on the new course of Professional education to be gone through by all persons seeking entrance into the Medical Profession, in order to secure the possession by them of the requisite knowledge and skill for the practice of their Profession," plunged the Council on its second day of meeting *in medias res*, and the subsequent discussions on the Visitation of Examinations, and on Dr. ACLAND's eloquent speech, ensured for this subject all the elucidation which a thorough debate could confer on it.

If the Council possessed the vantage ground on which we stand, of summarising the propositions made, and the opinions expressed on them, they would, we fancy, have commenced at the right end of the subject, and thus escaped their involvement in much needless discussion.

All the suggestions for Examination Reform which have been as yet promulgated, while differing in their *modus operandi*, start from one common principle. The object of all is to fix such a standard of education as will secure uniformity in all professional qualifications, and while Dr. ANDREW WOOD asks the Council to do so by affirming a minimum standard, Dr. ACLAND and Mr. RUMSEY hope to effect the object by establishing a Board of Examiners unconnected with any of the existing qualifying bodies, to act either in conjunction with them, or as a superior tribunal on a corrective principle, similar to that of the Examining Boards of the Army and Navy. Now, we venture to suggest that the first question to decide before proceeding to

frame a system for securing uniformity of qualification, is whether we want uniformity at all, and it is on this point and not on the mechanical details that the greatest diversity of opinion exists. It is not surprising, when the facts are constantly forced upon the Council, that a Dutch Auction of Diplomas exists in the Profession in which those Corporations who desire to maintain a high standard of professional competency are, by the competition of less scrupulous bodies, absolutely starved into a reduction of their requirements—that the amount of Medical capacity which the public have a right to expect from the profession, is taxed down to a disgracefully insufficient amount by a system which makes it impossible for high-class education to be maintained—when these considerations, we say, are before the Council, it is not wonderful that they should jump to the conclusion that a uniformity of qualification is the elixir for the disease.

On closer consideration, however, it seems evident that beyond a certain limit uniformity of education would be neither possible nor desirable. In the first place, it is plain that the Council could only, under any circumstances, fix the limit in one (the downward) direction, for they could not forbid a University from demanding any requirement which its position may enable it to insist on, and if a uniform standard were fixed, it must evidently be at the lowest limit which any qualifying body could be permitted to adopt. If there were a uniformity in the public standard of a doctor's competency, this could be done at once, *if* the Council had the power and would take the responsibility of dragging up the underselling Corporations to their own theoretic level, but as long as the public demand a gradation of medical advice from the Prescribing Druggist to the Consulting Physician—from the shilling to the guinea fee—we can hardly understand where the Council is to place its mark of competency. The qualification which confers capability to concoct antibilious pills, or draw teeth at sixpence a-piece, could not be considered sufficient for the treatment of cases of urgent importance; and the Council is hardly in a position to insist on what it knows to be a thoroughly reliable amount of Medical education on the part of practitioners, who, from their line of practice, can hardly be supposed to require it.

The inevitable result, moreover, of a minimum of professional education fixed by the Council and legally recognised as sufficient for all the purposes of medical practice, would manifestly be that that standard would be universally accepted by the Profession and by Licensing Corporations. Every further requirement will be regarded as an unnecessary tax on the student, and, inasmuch as the low-class qualifying Bodies will have a legalised ground-work for

their examinations, the Corporations who desire to maintain a high position would find themselves in a worse position than ever.

Thus, the Council being unable, from the existing public demand for cheap doctoring, to place its standard at a high scale, would be establishing a dangerous and mischievous precedent, without in any respect remedying the present grievance.

In this view of the matter, it is evident that the Council is not at present in a position to enforce a high standard of medical qualification, and, therefore, though we willingly concede that such a consummation is "devoutly to be wished," we must pronounce against both Dr. Wood's, and Dr. ACLAND'S schemes. A fixed standard is possible in France, because there it is in the power of the Government to place it wherever on the scale it may think fit, and from such determination there is no appeal. As a result, we have the very condition which we apprehend, for the fixed standard is the only standard, and no man can, even voluntarily, attain a higher *imprimatur*. The system also is carried out in the British Army and Navy, because the authorities are in a position to insist on any requirements they may desire; but until the Council is in a similar position of command, it would be useless to set down a standard which public convenience would forbid their maintaining.

Taking into consideration all the circumstances, we think that public competition at present provides as perfect a test of medical qualification as the Council could secure, and it would not be wise for them, by giving their legal countenance to a low standard of education, to discredit the efforts of Universities and Colleges, who are endeavouring, even at a loss, to main the intellectual position of the Profession.

#### SALE OF DISEASED MEAT IN DUBLIN.

It appears from the *Irish Times* that, within the last fortnight, about thirty oxen, sheep, and pigs, have been seized by the police, on the suspicion of their being diseased, and of these, nearly two-thirds were examined by Professor Cameron, and pronounced by him to be utterly unfit for use as human food. At the last sitting of the Lord Mayor's Court, as stated by the *Irish Times*, the seller and purchaser of a diseased pig were heavily fined. The carcase of the animal, it appears, was sold for 12s., to a sausage-maker, but was detected by the police on its way to the machine. Dr. Cameron deposed that it had died or been killed whilst suffering from a most loathsome disease, somewhat resembling scarlatina, and which is known under the name of "soldier." The flesh was red, and the skin covered with an eruption.

The *Irish Times* deduces from this narrative the conclusion that public slaughter-houses are required, and we concur in the opinion; but there is a still greater want—a spirit of independence in public journals which may induce them to do their duty to their readers, by making public the names and addresses of convicted persons, re-

gardless of the sacrifice of popularity amongst butchers and sausage-makers.

When a sausage-maker can buy a diseased pig for 12s., and after disguising its disgusting condition in the process of manufacture, can sell it at a profit of about 1200 per cent., he can easily afford to pay a fine, when once in a twelvemonth he may be detected, and he and the equally culpable vendor can well afford to persist in their atrocious and disgusting frauds, when they escape public recognition under the distinction of the "*seller and the purchaser.*" With the aid of the *South London Press*, a spirited local journal, the authorities have almost succeeded in stamping out the frauds in weight, quality, and purity of articles of consumption, which seem to have been almost the rule amongst the tradesmen of the districts south of the Thames. We can never hope for the attainment of a similar result in Dublin, as long as the editorial cloak is thrown round "the seller and purchaser."

#### THE PURGATORY OF PERIPATETICS.—II.

THREE weeks ago, in an article under this title, we gave a succinct account of the theory advanced by Dr. Chapman as to the cause of sea-sickness, and the means by which, in his opinion, it may be prevented, and we ventured to assert that it is the duty of those of our professional brethren, whose patients are about to visit the French Exhibition, to induce them to put the theory to the test in their trip across the Channel. Those of our readers who have done us the honour to carefully peruse that article, will, we doubt not, be disposed to admit that at least a fair case for inquiry has been made out. The theory is not only ingenious and original, but it is so intimately related to other important questions in physiology and therapeutics, and has been advanced with such confidence, and yet with such professional propriety by its author, that we thus early recur to the subject, in order to consider its strictly practical aspects. In doing so, it will be unnecessary to repeat even its outlines. Suffice it to say that Dr. Chapman believes that by modifying the temperature of the spinal region, we may produce most important curative effects in a great variety of diseases, and that as to the distressing malady under immediate consideration, the application of ice (in an appropriate india-rubber bag) to the spine, immediately arrests the vomiting, and if the remedy be employed early will as certainly prevent its occurrence.

In support of his statement, Dr. Chapman has already accumulated a sufficient number of successful cases to warrant any one in giving it a trial. In a pamphlet on the subject, he has detailed seventeen cases tending to show that this treatment is not only effective, but contrary to the expectation of many is particularly agreeable. According to the reports of his patients, it not only arrests or prevents the sickness, but the cramps or spasms that frequently accompany it, at the same time restoring the circulation to its normal standard, and so changing the pallid, cold prostrate condition of the victims of sea-sickness, to the ruddy, warm glow characteristic of health and activity of the circulatory function. Here then we have two distinct phases of the proposal to which to direct attention. First, the efficacy of the remedy; second, the agreeableness of the application. Each of these points deserves more space than we can afford for its discussion, but we will as briefly as possible touch upon each.

First as to the efficacy of the method. Amongst other evidence we find that Dr. Hayle of Rochdale had advised a patient to try it in a voyage across the Atlantic. The result was that "he was never sick when wearing the ice-bag. Once he went without it, and then, and then only, was he sick." Another interesting piece of evidence is the success with which it was used in the case of the son of Mr. Darwin, the eminent naturalist, in a voyage from Holyhead to Kingstown.

A lady, describing her trip from Dover to Calais, writes—"I think nearly every one was sick, and I, the usually worst of all, not only not sick, but even well. . . . We reached Calais, and I had not experienced the slightest nausea." Another lady, who always suffered at sea before resorting to the ice-bag, and on two occasions had had epileptic fits induced by the ship's motion, made five comfortable passages between Folkestone and Boulogne. A third lady, who had been six times at sea and suffered each time, went from Newhaven to Dieppe "without experiencing the least sickness." Other evidence of an equally conclusive kind is adduced, but as we cannot find room for it all, we will select the testimony of Dr. B. Lee, an American physician, and who, being far removed, may be supposed to be as impartial as any. This gentleman relates a case in the *Philadelphia Medical and Surgical Reporter*, and then adds the following remarks:—

"If Dr. Chapman has proposed to us a means of alleviating, with almost perfect certainty, that most distressing malady, sea-sickness, we are criminally neglectful if we refuse to employ it. . . . The case (in question) is as conclusive as a single case can be, in regard to the great practical value of his discovery. . . . The effects of the application of the ice-bag were little short of miraculous. In three minutes the retching ceased and the spasms were calmed. In a quarter of an hour she (the patient) had fallen into a quiet sleep; and in half an hour her hands and feet were of natural warmth, and her face had regained its wonted colour. In two hours she awoke, greatly refreshed, and from that time did not miss a single meal. I can see no reason why the process may not be successfully extended over twelve days as well as four (the treatment was continued during the whole voyage—a rough one, lasting four days and a half—with complete success), with proper care and management."

So much for the efficacy of the ice-bag. We pass now to the second point—the alleged comfort of the application.

It is not surprising that many people should regard the idea of applying a column of ice to the spine with a considerable degree of apprehension. Before Dr. Chapman demonstrated its safety it would generally have been pronounced dangerous, and a casual remark in Dr. Todd's Clinical Lectures shows that even that experienced Physician would have hesitated to employ it. It would seem, however, from numerous instances, that, properly applied, the ice is not only safe, but positively pleasant. Of course, the immediate arrest of the sickness is in itself a comfort which most people would gladly purchase at the expense of a painful process. But not only is the ice not painful, but, according to the testimony of the great majority of patients, quite the reverse. Besides staying the sickness and cramp, when present, the ice-bag restores the cutaneous circulation, so that the extremities become warm. Then the irritability of the stomach is so effectually subdued that light food can soon be taken, and the return of the appetite is very commonly reported.

Moreover, the soothing effect is so general, that sound and refreshing sleep is frequently induced, so that we constantly read of patients—men, women, or little children—falling asleep on the ice-bag, and waking up refreshed and hungry.

If the theory which we have so fully explained be correct, these results might have been predicated, for they are but the natural effects of a remedy acting in the manner proposed. Still, as not a few may be glad to have some of the encouraging facts before them, we will give from Dr. Chapman's detailed reports the following striking statements respecting the agreeable effects of his mode of treatment, as the most likely method of inducing our readers to collect still further evidence.

Case 1.—"I think nearly every one was sick, and I, the usually most of all, not only not sick, but even well, feeling as if I were in a cradle, being rocked by the gentle hands of a tender nurse. . . . I don't know, of course, the effects of ice on a long-continued voyage, but I venture to believe that the feeling of perfect comfort would continue as long as the ice is kept on."

Case 2.—"Felt the cold to the back peculiarly grateful, but wished it more intense; bag therefore placed next the skin. This change delighted her."

Case 4.—"Ten minutes after vessel started, became violently sick; muscular effort extreme; said, 'I think my heart is coming up!' Applied ice along the entire spine as quickly as possible, *instantaneously* relieved, lay down upon the ice soothed and calm."

Case 6.—"About twenty minutes before reaching Boulogne, ice in bag so nearly melted, that felt the refreshing and sustaining influence of the cold lessening; placed an additional bagful of ice outside dress, over bag already supplied; this sufficed to restore the agreeable sensations hitherto enjoyed, and to continue them until at Boulogne."

Case 9.—"During the second two hours (of the passage to Dieppe) was fast asleep—lying on the ice. . . . Particularly impressed with the relief afforded by the ice, from the great suffering in the head, had always experienced at sea."

Case 10.—"After lying upon the ice, both sickness and headache ceased entirely."

Case 11.—"Was lying down very sick with acute headache. Was laid on a bag of ice, the bag next the skin. The head became quite free of pain in a few minutes. . . . Still lying on the ice, fell asleep. In about half an hour awoke quite well, and continued so."

Case 12.—"Put on an ice-bag; felt ill about fifteen or twenty minutes, then rapidly recovered; all nausea, sweating, and chilliness ceased; the colour returned to my face, as observed by the captain and some of the passengers; the troublesome threats of diarrhoea and uncomfortable sensations in the bowels passed away, and I continued quite well—really enjoying the remaining five hours of the passage to Dieppe. I wore the ice nearly the whole time."

Case 14.—"Felt the cold agreeable and refreshing; in a few minutes said he felt better; before long expressed astonishment at finding all uncomfortable sensations, together with nausea, wholly gone."

Case 15.—"Fears the sea so much as to be in a fright the whole time; this time was not frightened at all after the ice had been applied."

Case 16.—"Soon became warm, and fell asleep with the ice on her back. She awoke very hungry, and quite well."

Case 17.—"She was so delighted, poor creature, she thanked me a thousand times. The ice made her quite well, and she went to sleep with it on her back."

## Notes on Current Topics.

THE PRINCESS OF WALES.—At length it appears that the improvement we have mentioned in the state of the Princess of Wales has become decided. It is well-known that, at the request of the medical attendants, Mr. Heather Bigg has arranged a mechanical support for the limb, which has proved very comfortable. After a time it

is believed that this may be dispensed with, and that in the end the use of the joint will be restored. On Monday last Mr. Bigg adjusted the support so as to permit of carriage exercise.

UNIVERSITY REPRESENTATION.—This question has been prominent during the week. After a most obstinate contest the House of Commons has rejected the proposition of the Government to unite the University of Durham with that of London. Nothing but the most earnest work and thorough determination on the part of the friends of the London University would have saved it from the danger by which it was threatened. It is quite astonishing how any Government could have seriously insisted on such a proposal. The outcry of the organs of public opinion against the incongruous union was almost universal, yet the Government persevered. The battle was long and uncertain, but victory at last fell to the metropolitan seat of learning, and probably no further attempt will be made to neutralise its influences. As to the Scotch Universities several other names have been mentioned as likely candidates, but up to this time nothing very decisive has transpired. Dr. Clark is likely to be well supported for Glasgow and Aberdeen. For Edinburgh and St. Andrews a medical graduate will only, with difficulty, be secured, unless the St. Andrews Association should be as successful as it is hoped. Another meeting was held on Wednesday, which shows that the Society is likely to take a firm hold on the general body of graduates. A report of the meeting will be found at page 611.

SHOCKING CASE OF MORTALITY.—A person named Carter resides at Newcastle, on the Barrack-road, opposite the Leazes, in one of a row of houses which, although situated in the healthiest part of the town, are badly drained, the road unpaved, whilst a lane at the back is described as being in a disgustingly filthy state. This man had five children, who were all well on Saturday morning. In the evening one of them died with all the symptoms of pestilential fever. On Sunday another child died, and on Monday another. On Tuesday when the parents returned home from burying these three children they found a fourth just dead, and on Wednesday night the fifth and last succumbed to this fearful disease, the origin of which is attributed by the neighbours to the want of necessary sanitary precautions. In reference to this, it may not be out of place at this season to direct attention to a common cause of disease in the neighbourhood of London and other large towns. Land let for building purposes is excavated for brick-making during the summer. A notice is then stuck up, that "Rubbish may be shot here." The holes are filled up during the winter and spring with the refuse of dust-yards and other abominations, animal and vegetable, in which, when somewhat solidified, the foundations are laid and the road made. Is it to be wondered at if the action of the summer's sun converts this into a seething mass of corruption, polluting the atmosphere and poisoning the inmates?

UNIVERSITY COLLEGE, LONDON.—This Council held a special meeting for the award of the Atkinson Morley Surgical Scholarship (£45 per annum for three years) on Saturday, the 15th of June, Founder's day. The scholarship was conferred on Mr. George Vivian Poore, of Andover. The examiners were Professors Erichsen, Wharton Jones, and Marshall, and Mr. Berkeley Hill.

## Foreign Medical Literature.

### INVESTIGATIONS RESPECTING ARTERIAL DILATATION AS A RESULT OF NERVOUS IRRITATION.

By Dr. CHRISTIAN LOVEN.

TRANSLATED FROM THE "HYGIEA" FOR NOVEMBER, 1866, p. 425.

By WILLIAM D. MOORE, M.D., Dub. et Cantab., M.R.I.A.; HONORARY FELLOW OF [THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN]; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

The following essay is a translation of an account of the investigations instituted by me in the winter of 1865-66, in the Physiological Laboratory at Leipsic, under the direction and with the able co-operation of Professor C. Ludwig, which was published in the *Berichte der kön. Sachs. Gesellschaft der Wissenschaften, Mathematisch-Physische Classe*, for May, 1866. Partly because this journal is little circulated here, partly because the essay relates to various questions which ought to possess great interest also for the practical physician, I have not hesitated to comply with a request that I would publish it in Swedish, and I also seize the opportunity of publicly acknowledging the great obligation under which I lie to Professor Ludwig, without whose active assistance my investigations would probably not have fulfilled their object. I am the more anxious to do this, as, with the liberality characteristic of him, he has not permitted any reference to my obligation to him in the German original:—

1.—*Changes in the cardiac impulse and in the pressure of the blood, which occur during irritation of a sensory nerve, being in connection with the brain and spinal cord.*

Every painful irritation of a sensory nerve produces, in a healthy animal, such numerous phenomena, all of which may alter the current of the blood, that it would be impossible in this mode to investigate the relation between irritation and change in the circulation. The attainment of this object first became possible, when we obtained the aid of *Curare*. Principally with the employment of this poison have I instituted the following experiments upon this subject in the physiological laboratory in Leipsic.

The phenomena observed in poisoned animals after irritation of sensory nerves, consist in changes in the impulse of the heart, in the diameter of the small arteries, and in the pressure of the blood. As changes in the cardiac impulse, and in the pressure of the blood in themselves give us two conditions capable of acting on the bore of the arteries, we must evidently first inquire how, and under what circumstances, the cardiac impulse and the pressure of the blood vary, before we can enter upon the solution of the question, what direct connection exists between the sensory irritation and the change in the diameter of the vessel? So far as I know, von Bezold is the only investigator who has instituted experiments to determine the state of the impulse of the heart, and of the pressure of the blood after a sensory irritation. Important as the results collected by this distinguished physiologist are—they were, because his experiments were undertaken from other points of view, not sufficient for my object, on which account I found myself compelled in some respects to complete them. Before proceeding to give an account of my experiments, I will, as briefly as possible, state the results obtained by Von Bezold. The animals of which he made use were, with few exceptions, poisoned with *curare*, and the trunks of the vagi and sympathetic nerves were divided in the neck. Moreover, in various series of experiments, several changes in the brain and spinal cord were produced, principally consisting in this: that an incision was made either beneath or above the medulla oblongata; lastly, in some cases the brain and spinal cord were left untouched. The irritation was applied either to the sensory spinal nerves or to the central extremity of the divided vagus.

(a.) Brain and spinal cord in their normal state; irritation of the brachial or ischiatic plexus. The cardiac im-

pulse became harder, and the pressure of the blood began to increase immediately after the irritation.

(b.) The medulla divided above or below the medulla oblongata; irritation of sensory spinal nerves. Pressure and cardiac impulse continued unaltered.

(c.) Medulla oblongata separated by an incision from the rest of the brain; irritation of the central stump of the vagus on one or both sides. The pressure of the blood falls immediately after the commencement of the irritation, the number of heart's beats is diminished, and after the cessation of the irritation the pressure of the blood does not reach the height it had before the application of the irritant.

(d.) Brain and spinal cord in their normal state; irritation of the central vagus stumps. In this mode of instituting the experiment either a sinking or an increase of the pressure of the blood occurred directly on the commencement of the irritation. In some cases the pressure remained, so long as the irritation continued, either at its elevated or depressed value. In others, on the contrary, an increase or diminution of the pressure over or below the normal value, alternated with each other during the experiment. If the pressure was increased the number of the pulsations was also increased.

These facts leave it undecided, whether the increase of the pressure of the blood depends upon an elevation of the heart's action, or upon increase of resistance in the course of the circulation. To ascertain this so far as I could, I determined to alter the experiment by, in opposition to von Bezold, leaving the vagus uninjured. Moreover, I directed my attention to the state of some small arteries in the ear and hind leg. In the last named extremity I was accustomed to expose the saphena artery, which, as is well-known, is remarkable for its irritability. If the auricular vessel was observed, the central end of the posterior or anterior auricular nerve was irritated; if, on the other hand, the arteria saphena was exposed, the central portion of the nervus dorsalis pedis was tetanised. The results obtained from three animals are given in the subjoined table. To these a series of observations is added from a fourth animal, in which the nervi vagi were divided during the course of the experiment:—

OBSERVATIONS ON THE LEG.

	Mean pressure in the Carotid Artery.	Number of the pulse in the same time.	Diameter of the Arteria Saphena
I.			
1. Before poisoning with curare . . . . .	86	100	
Poisoning without irritation . . . . .	89	100	
Irritation of the nervus dorsalis pedis . . . . .	126	49	Diminished.
Irritation of the nervus dorsalis pedis . . . . .	101	52.5	Increased.

\* The diminution of the frequency of the pulse, and the increase of the pressure of the blood, occur also after mechanical irritation of the auricular nerve. In all cases the pulse does not become slower, until after the pressure has considerably increased.

If we now put together in words what is contained in the above table, it thence appears that:—

(1.) The pressure of the blood is in the unpoisoned animal usually lower than in the poisoned; the number of the cardiac pulsations may, at the same time, be less or greater in the poisoned animal than in the unpoisoned. I would here remind the reader of the well-known fact, that the small arteries become remarkably more compressed in consequence of poisoning with curare.

(2.) After irritation of the auricular nerve, as well as of the nervus dorsalis pedis, the number of the cardiac pulsations is invariably diminished, and in spite thereof the pressure of the blood increases very considerably. The curve of pressure at the same time exhibited this peculiarity, that the periodical elevations and depressions, which before and after the irritation were caused by the artificial respiratory movements, now disappeared. All these particulars show, that the increase of the pressure is by no means attributable to increased action of the heart, but rather to an obstruction to the efflux. This view is corroborated by the experience noted in the fifth column of the Table. If, in fact, the pressure of the blood increased considerably, notwithstanding that the heart's pulsations became slower, the visible small arteries had contracted to the disappearance of their bore. If, on the contrary, the pressure of the blood sank under irritation, the arteries became dilated.

However, the pressure of the blood in the six instances, in which, according to the Table, the arteries observed became dilated, did not sink below its value previously to the irritation, but fell, in the most favourable case, only to the degree it occupied before the irritation. As dilatation of the arteries must necessarily be attended with a diminution of resistance, we might expect that the pressure of the blood would sink beneath its normal value. Two ways are open to us to find an explanation of this absence of the expected result. Either the force of the heart is increased—against this assumption the numbers in the Table, without exception, tell, for these show, that even where arterial dilatation has occurred, the number of the heart's pulsations was less than before the irritation. We are, therefore, it seems to me, referred to the other mode of explanation. This would then require the assumption that the dilatation had not extended itself to all arteries, but merely to precisely that which was observed, and perhaps to some others, while a more or less considerable contraction remained in all the others. I am the more inclined to lean to this hypothesis, since, as my observations, to be presently communicated, prove, the dilating influence of a sen-

sory nerve does not in general extend beyond the peripheral region of expansion of the nerve in question; and, in very fact, I had also observed precisely the artery, whose special nerve was irritated. Otherwise, it is evident that many experiments are desirable towards clearing up the actual circumstances of the matter.

(To be Continued.)

### THE ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

THE second meeting of this Association was held at the Freemason's Tavern, Great Queen-street, on the 19th inst. On this occasion it was agreed to keep up the union of the Graduates by an annual session, commencing on St. Andrew's Day, or such other day as the Council might determine, and that the meeting should terminate with a dinner. It was decided that at the annual session, the discussion should be not only for the advancement of the science and art of medicine, but for that of general science and literature, the maintenance of the interests of the medical graduates of the University, and the cultivation of social intercourse and good fellowship.

The minutes of the last meeting were read by Dr. Leonard Sedgwick, the Honorary Secretary, and unanimously agreed to.

Dr. RICHARDSON (chairman and president) said the letters received were too numerous to read, and that the members already numbered 253, and many other graduates had expressed their intention of joining. In sixteen days, more than 250 names had been added to the list. The last meeting was especially convened for the consideration of the subject of their enfranchisement, but on the present occasion they met not only to establish the Association, but to found it on such a basis that it should be permanent after the present cause for their union had passed away.

Dr. M'INTYRE said he had written to Mr. Slater Booth, and read a letter from Mr. Beech to say, that a satisfactory clause would doubtless be introduced, and another which stated that the subject would be considered by the Lord Advocate.

Dr. RICHARDSON said that thirty Members of Parliament could be obtained on their side. He wished that the Association should be a distinct organization, meeting at a central place annually, and also that there should be a dinner. He had seen Mr. Ellis, the Member of Parliament for St. Andrews, who advised that there should not be a deputation to Government. Dr. Paul, the treasurer, was prevented from coming, but he would state that £53, 15s. had been received, of which they had £40 in hand.

The rules were proposed and seconded *seriatim*. There was a long discussion as to whether the associates should be elected or admitted on payment of their subscription, and to prevent the presence of objectionable members, a penal clause was proposed, but the suggestion was not acted upon, and the rule for their admission finally passed runs as follows:—"That all legally qualified medical practitioners be eligible as associates on election by the Council."

Dr. DRYSDALE strongly advocated the principle of examination followed in the St. Andrews and London Universities, and expressed his opinion that a degree should be general in the profession.

Dr. M'INTYRE drew attention to the Bill, and said he thought it would be satisfactory, if the offending clause were removed, or the date 1833 placed instead of 1863.

Dr. RICHARDSON refuted an idea which, he thought, was rather general, namely, that St. Andrews degrees had at one time been sold without examination, and read a letter from the Registrar stating that that was never the case.

Drs. SEDGWICK and WYNN WILLIAMS showed that a very considerable number of St. Andrews graduates were on the staff of the different public charities, and that twenty-four were connected with the London and provincial medical schools.

The following is the list of officers elected for 1867-8:—

*President*—B. W. Richardson, M.A., M.D., F.R.S., London.

*Vice-Presidents*—Henry Day, M.D., Stafford; Dr. Thiselton Dyer, London; Dr. Greenhalgh, London; Dr. and Inspector-General Leonard, Norwood; Dr. Tanner, London; Dr. Wyse, Dublin.

*Council*—Dr. G. Balfour, Edinburgh; Dr. T. Ballard, London; Dr. Edwards Crisp, London; Dr. Collett, Worthing; Dr. Crawford, Peebles; Dr. D. Davies, London; Dr. Davey, Bristol; Dr. Drysdale, London; Dr. Dudfield, London; Dr. Fayer, Henley-in-Arden; Dr. Dean Fairless, Coupar-Angus;

Dr. Day Goss, London; Dr. P. Hood, London; Dr. Prosser James, London; Dr. Walter Jones, London; Dr. Mackinder, Gainsborough; Dr. M'Intyre, Odiham; Dr. Minter, Southsea; Dr. Nichols, Devizes; Dr. Procter, York; Dr. Roden, Kidderminster; Dr. Joseph Rogers, London; Dr. Lloyd Roberts, Manchester; Dr. Seaton, Sunbury; Dr. Sheppard, Colney Hatch; Dr. Skinner, Liverpool; Dr. Abotts Smith, London; Dr. Spencer Thompson, Torquay; Dr. Tuke, London; Dr. Uvedale West, Alford; Dr. Wynn Williams, London.

*Honorary Treasurer*—Dr. Paul, Camberwell.

*Honorary Secretary*—Dr. Sedgwick, 2, Gloucester-terrace, Hyde-park, London.

### PROPOSED RULES.

1. That the Association be called THE ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

2. That the objects of this Association be the advancement of the Science and Art of Medicine, the maintenance of the interests of the Medical Graduates of the University, and the cultivation of social intercourse and good fellowship amongst them.

3. That the Association consist of Members, Honorary Members, and Associates.

4. That all Medical Graduates of the University of St. Andrews be eligible as Members.

5. That all Members of the General Council, all Professors, and all non-medical Graduates of the University of St. Andrews, be eligible, on election, as Honorary Members, as well as such other learned and scientific men as may be elected at a General Session, on the recommendation of the Council.

6. That all legally qualified medical Practitioners be eligible as Associates.

7. The subscription constituting a Member or Associate shall be Five Shillings, payable on the 1st of January annually.

8. The Officers of the Association shall be elected from the Members, and shall consist of a President, Six Vice-Presidents, a Treasurer, a Secretary, and a Council of Thirty-two; in whom the power of framing bye-laws, and of directing the affairs of the Association, shall be vested.

9. Five members of the Council shall form a quorum.

10. The Officers of the Association shall be elected by ballot at the General Anniversary Session of the Association.

11. The President, Vice-Presidents, and Council, shall be eligible for re-election, except that of the Vice-President's two, and of the Council eight, shall retire every year.

12. The business of the President shall be to preside at the Annual and Extraordinary Sessions of the Association, and at all Meetings of the Council; in his absence one of the Vice-Presidents, or the Treasurer, or any Member of the Council chosen by the Members present, shall take the chair.

13. The Treasurer, or some person appointed by him, shall receive all moneys due to the Association.

14. The money in the hands of the Treasurer, which shall not be immediately required for the uses of the Association, shall be vested in such speedily available securities as shall be approved of by the Council.

15. The Council shall lay before the Members, at each Anniversary Session, a report of their proceedings during the past year, and also an account of the receipts and expenditure of the Association.

16. The Council shall meet at least once in two months, unless by special resolution to the contrary.

17. The annual accounts of the receipts and expenditure of the Association shall be audited by a Committee of three Members, selected at the preceding Anniversary Session from among the Members at large.

18. The Secretary shall have the management of the general correspondence of the Association, and of such other business as may arise in carrying out its objects.

19. That the Association shall hold an Annual Session, commencing on St. Andrew's day, or on such other day as the Council may determine. The place of such Session, its duration, and the business to be transacted, shall be arranged by the Council.

20. That the Members and their friends shall hold an Anniversary Dinner on the last day of each Annual Session, at such place and time as the Council may determine; the President for the year shall be in the chair.

21. No alteration in the Laws of the Association shall be made, except at a General Session. Notice of the alteration

to be proposed must also have been laid before the Council at least a month previously.

22. The Council shall have power to call a General Session of the Members at any time, and shall also be required to do so within one month, upon receiving a requisition in writing to that effect from not less than twenty Members of the Association.

23. All Special General Sessions of the Association shall be held at such place as the Council may appoint.

## Correspondence.

### "TREATMENT OF AGUE BY HEAT TO THE SPINE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your paper of the 5th inst. there appeared an interesting letter on the treatment of ague and cholera by heat to the spine, concerning which I think it desirable that I should make a few remarks.

In accordance with the neuro-pathology and therapeutics exemplified in my reports of the several cases of epilepsy and paralysis already published in your columns, I have advocated the use of cold along the spine during the cold stage of fevers, and of cholera—which I regard as a form of fever, with an extremely prolonged cold stage.

"I have had but slight experience in the treatment of fever, but I anticipate that fevers of all kinds will be most effectually controlled by cold along the spine in the cold stage, when the blood-vessels are contracted, and heat in the hot, when they are relaxed. I apprehend that the prolonged stage of the so-called *fièvre algide*, common on the shores of the Mediterranean, may be cut short by means of ice. Of course, in cases of fever due to zymotic poisons, this treatment cannot remove the cause; but neither can any known treatment do so. Cold in the cold stage, and heat in the hot, will, however, I predict, exercise an effective controlling or restraining influence on all forms of fever, the exanthemata included."\* Moreover, the whole purport of the work from which this passage is quoted is to prove, both by reason and experience, that the most scientific and successful method of treating cholera during every stage of its development until reaction sets in, consists in the appropriate application of cold along the spine.

The recognition by an "M.D., M.R.C.P. Lond.," that such important diseases as ague and cholera may be most successfully treated by modifying the temperature of the spinal region, is a step onwards towards the establishment of my pathological and therapeutical views, and therefore gives me much pleasure. As, however, the interesting facts he mentions seem at first to contradict those views, his letter suggests some important questions which I proceed to state and answer.

1. Seeing that I advocate the application of cold along the spine during the cold stage of ague, whereas "M.D.'s" experience is that heated bricks, wrapped up in cotton cloth and applied "to the spinal cord," rapidly cut short "the cold stage of ague, even on first application," the questions arise—Can the two methods, so opposite to each other as they are, be right? If not, which is right?

2. Seeing that I advocate the application of cold along the spine in cases of cholera until reaction sets in, whereas "M.D." says, one of the native doctors told him that he used the "hot treatment in cholera, by means of braziers of hot fire, *i.e.*, live charcoal, put under the bamboo couch, on which his cholera patients were laid naked, then covered over above, except the face, with thick warm clothing;" and that "the intense cramp and suffering of this unknown malady was checked remarkably with cessation of rice-water evacuations and vomiting"—the relief being "invariably followed by copious offensive discharges from the bowels the next day," the same questions arise as in the former case, *viz.*—Can the two methods, so opposite to each other as they seem, be right? If not, which is right?

3. If one only of these methods is at once scientifically correct, and therapeutically successful, why is there a semblance of right in the other?—or, in other words, what is the significance of the success in the treatment of the cold stage of ague and cholera, which "M.D." reports.

In the first place, physiological and pathological facts afford strong reasons for believing that during the cold stage of ague, the spinal and sympathetic nervous centres are hyperæmic, and that therefore ice applied along the spine is likely, by lessening the hyperæmic condition, to cut short the rigor. I need only allude to the fact, now so well established, that by section of the cervical sympathetic, an afflux of blood to the head is induced, and that by galvanising the cut end of the upper part of the nerve, the blood vessels of the head are made to contract. Now, the application of ice along the lower cervical and upper dorsal spine, produces an effect of a kind like to that resulting from section of the nerve, an effect, however, far short, of course, of the total paralysis caused by the knife. On the other hand, the application of heat along the same region, stimulates the nervous centres, and thus produces effects analogous to those produced by galvanism of the sympathetic, *viz.*—contraction of the blood-vessels controlled by the branches of the nerve influenced, and, therefore, coldness of the parts amid which those vessels ramify. The recognition of these facts seems to lead inevitably to the conclusion that during the cold stage of fevers, ice applied along the spine is likely to prove beneficial, and that when reaction sets in, heat should be applied along the same region.

The accuracy of this conclusion is proved by a large number of pathological and therapeutical facts which I have observed and recorded. The coldness and pallor which accompany seasickness, quickly give place to the ruddy glow of health when ice is applied along the spine. In several of the cases of epilepsy and paralysis reported by me recently in this journal—cases in which the extremities had been remarkably cold for long periods, sometimes for years—a normal circulation was re-established, the cold limbs becoming quite warm under the influence of the spinal ice-bag. I also mentioned one case in which a hot head was made cool by the application of heat to the spine. I could adduce a large number of like cases, but the most decisive proof of the power of heat appropriately applied on each side of the spine to contract blood-vessels, consists in the evidence which I have published, that menorrhagia can be most effectually and rapidly arrested by the application of heat along the lumbar and lower dorsal region. In presence of these facts, I feel constrained to express my strong opinion that the application of heat to the spine during the cold stage of ague, is not likely, as a general rule, to be attended with benefit, and that it may prove dangerous; whereas both science and experience counsel the use of cold during this stage.

As already said, I regard cholera as a fever, the cold stage of which is extremely prolonged; and, as I hold the opinion that during the whole period of this disease until reaction sets in, the arteries in nearly all parts of the body [I have indicated the exceptions in my work on *Diarrhoea and Cholera*] are spasmodically contracted more or less according to the stage and intensity of the disease, I am, of course, led by the facts and reasoning above-mentioned, to apply ice so long as any algide symptoms remain, just as I should do throughout the cold stage of ague. And again I feel bound to express, as strongly as possible, my conviction that the application of heat along the spine during any stage of cholera before reaction sets in, will both distress the patient and tend to hasten his death. Notwithstanding the extremely adverse circumstances under which the method of treating cholera patients by means of the spinal ice-bag was tried in Southampton in 1865 and 1866, twenty-six out of thirty-three patients in collapse were completely rescued from that state, and four more were rallied—two of them to a great extent. I have also published other cases in which the application of ice to the spine of patients in collapse, resulted in the speedy arrest of the cramps, vomiting, and purging, and the production of a steady reaction from the algide state. On the other hand, when reaction has fairly set in, and by developing into fever becomes dangerous, it may be controlled, as I have proved experimentally, by the application of heat along the spine: a case was published some time ago, in Calcutta, which exemplified, in the most signal manner, the power of the ice to recover the patient from collapse, and the power of the heat afterwards to assuage and subdue the reactionary fever. My doctrine that the application of heat along the spine during choleraic collapse is both distressing and dangerous, receives some confirmation from the statement of Dr. J. Wilson Macloy, who last year treated seven cases of cholera at Liverpool, by means of cold and heat to the spine. He used the two alternately, and he says—"While the ice-bags to the spine were borne without complaining, a similar application of water at 120° Fahr., caused the greatest pain."

\* "Diarrhoea and Cholera: their Nature, Origin, and Treatment, through the Agency of the Nervous System. By John Chapman, M.D. 2nd edition, enlarged, pp. 15-6.

All the seven patients died—a result which was far from surprising me.

In conclusion, I will give what appears to me to be the correct answer to the third question, which I have propounded, viz.—assuming the doctrines above expressed, what is the significance of the success in the treatment of the cold stage of ague and cholera by means of heat, which “M. D.” reports? I must observe, in the first place, that it is impossible to discuss this question satisfactorily without more precise knowledge of “M. D.’s” case of ague, than he has supplied. He does not say how long the hot bricks were applied, and whether they were applied lengthwise, along the spine only, or over the back generally. But taking the case as he reports it, I explain the good result obtained as one of reflex action, and as analogous to the alleged action of a cold key, when put down the back, in arresting bleeding from the nose. The whole amount of iron in an ordinary door key is small, and therefore, when it is applied to the spine, the amount of heat which it can abstract is small, and consequently it quickly ceases to exert any direct influence, even if allowed to remain in contact with the spine; but, in fact, as I am told, the key is passed down the back, allowed to fall between it and the clothes, and is then picked up and reapplied. Now, in this way, a sudden but transitory impression of cold is transmitted to the spinal cord, and this is quickly followed by a corresponding but more enduring reaction, which consists in a slight preternatural afflux of blood in the nervous centres, or, in other words, a condition like to that which would be induced by the application of a moderate degree of heat. It is this condition of the nervous centres thus induced, which is the proximate cause of the arrest of the hæmorrhage. And, in like manner, though conversely, when heat is applied to the spine for a short time, as in the case of the hot bricks wrapped up in flannel, their application, if restricted to the spinal region, only causes in the nervous centres acted upon temporary hyperæmia, which was, I apprehend, followed, in the case in question, by a more enduring reaction, resulting in anæmia of the same centres—anæmia which necessarily ended the cold stage of the ague fit.

In respect to the report made to “M. D.” by the “native doctor,” who used the “hot treatment in cholera,” I must premise that the report does not seem to me reliable, for it states that after the occurrence of “rice-water evacuations,” copious offensive discharges followed the treatment, whereas I am not disposed to believe that such discharges occur during the first stages of recovery in cases of algide cholera, where there have already been copious rice-water evacuations. But even admitting the truth of the native doctor’s statement, his results are in no sense inconsistent with the method of treatment which I advocate: to place a patient naked on a bamboo couch, to cover him over with thick warm clothing, and to put beneath the couch “braziers of hot fire, *i.e.*—live charcoal,” is merely to give the patient a hot air-bath in an eastern fashion. The heat in this case is not concentrated along the spine, but diffused over the surface of the body generally, and undoubtedly acts very beneficially in facilitating the return of the blood to the surface of the body. If superadded to this process an ice-bag were simultaneously applied along the spine, and were carefully guarded from the surrounding heat by non-conducting material, my method of treatment would be exactly realized, and the patient would, I am sure, have a far greater chance of recovery.—I am, Sir, yours truly,

JOHN CHAPMAN.

#### PREVENTION OF VENEREAL DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with great interest the reports of the several meetings, held by the Venereal Committee of the Harveian Society, as published in your valuable journal, still, it appears to me, that the Committee entirely overlooks the true primitive cause of the propagation of the venereal disease, for surely it is not the women who first infect the men, but, on the contrary, the men who first communicate the disease to the women; consequently, I am afraid that the labours of the Committee will be in vain, if some means are not found to prevent men from infecting the women.

To submit the unfortunate girls of this country to the police regulations which are inflicted upon them on the Continent, would be both useless and degrading. It is known that in Vienna, Paris, Berlin, and every other large town of the Continent, the hospitals are filled with the most inveterate and appalling cases of venereal diseases, and that in spite of the

weekly medical examinations of these unfortunate women. And this is easily understood, for suppose that a woman who is, let us say, examined to-day, has been contaminated a few hours after her last examination, of course the disease will only be visible in a day or two, so that the poor woman will innocently communicate the disease for five or six days until she is examined again.

I have also read a report of the Society for the rescue of young women, &c., &c., and I see that through the labours of this admirable Society, about 1000 of these poor girls are yearly rescued in England. Now, sir, I am confident, that if these medical examinations take place in the United Kingdom, there will not be the fourth of that number.

These exposures by *ordonnance* degrade them in their own eyes, and they soon lose all self-respect. It is not all at once that a young girl lately seduced loses her modesty; but then, *if by law* she is to submit herself to the most degrading inspection, she will soon not care to what abuses she is put, the vice will soon lose all its horrors, and she will fall to the lowest grade of libertinage without the slightest hope of redemption.

I will say, then, that to submit these poor girls to a medical examination, in order to eradicate this horrible disease, is to begin by the wrong end. We know that these unfortunate girls were once pure and innocent children—the delight of their parents. We know that a great many of them are often seduced and abducted before they have attained the age of discrimination, and left destitute on the streets, after the transient passion of their seducers has been satisfied. They are not, then, the originators of the disease, but *its victims*.

Why not then first examine the men, who are truly the originators and propagators of the disease?

Could not every house resorted to by these poor girls, be registered, and open under a heavy fine, to receive strangers during certain hours only, say from 4 P.M. to 12? A medical man, paid out of the registration money, could be attached to each house, in order to examine every man who would resort to it during the said hours. Means might be found, a mask for example might be used to save their *modesty*.

If I do not make a mistake, some stringent regulations as regards men would tend more to the eradication of the venereal diseases, than all the examinations of women. I know that the examination of men will not be quite so attractive as that of women, but it will be conducive to much more certain and happy results, being besides much easier and not compulsory as that of the women, for the men who would be examined would have nobody but themselves to blame for it.

I trust this view of the subject will be taken into consideration by every person interested in the matter, and especially by the Harveian Society, and the Society for the rescue of young women, &c., &c.

By the Harveian Society, in order to devise the best means to protect and prevent the women from falling the victims of the immorality of men—I say immorality, for their is no excuse for men in a state of disease to go and communicate it *knowingly* to any woman.

By the Society for the rescue of young women, &c., &c., in order to use their influence to prevent Parliament, *if necessary*, from passing a measure comparatively useless as far as prevention of the disease is concerned, and so much calculated to annul their noble and generous efforts for the rescue of these unfortunate and ill-used women.—I have the honour, &c.

E. L.

#### THE COUNTY INFIRMARIES OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—There is a subject closely affecting a large section of the Medical Profession in Ireland, as well as the public in general, which, in these days of reform, I think you, as the editor of THE MEDICAL PRESS AND CIRCULAR, bearing in mind your motto—“Salus Populi”—might do good service in noticing.

I allude to the County Infirmaries of Ireland. On examining Churchill’s Directory for this year, I find that, excluding Dublin and Cork, there are some thirty of these institutions, affording bed accommodation to nearly 1600 patients, and these 1600 sick people are cared for by thirty-six surgeons and physicians only. Indeed, but three county infirmaries—viz., Limerick, Kilkenny, and Westmeath—have more than one medical man attached to them. This state of things I consider unjust, not only to such as may require medical or surgical aid, but also

to the public and the Profession generally— unjust to the Profession because, whoever holds one of these appointments, holds also what may be called a monopoly of the surgery of his district, as nearly every surgical case of moment finds its way, almost as a matter of course, to the Infirmary; unjust to the public generally, because, if these appointments were not so exclusive, but distributed (as in England and Scotland) amongst the practitioners of the county town in which they are situated, the probability is that a greater number of medical men would be found in country districts, necessarily better qualified by daily routine to undertake any operation or surgical manœuvre; and unjust also to the patients who have to seek the assistance of these institutions, and who are obliged to trust in most instances to the judgment of one person alone, however skilful and competent he may be, instead of having the advantage of the advice of other medical men of the locality. Does not this state of things, sir, require redress? In English and Scotch counties they never dream of electing one gentleman alone to such a situation, chosen—as in this country he often is—not so much from his skill and acquirements as for strong local influence, giving him, too, a large salary, thereby diminishing funds which should be spent in charity—and in many instances assigning the best apartments in the house, which might be very much better applied in affording the inmates a greater cubic space to recover in. I would contrast such places as Londonderry and Antrim with Kilkenny and Westmeath, and I cannot see why the latter should appear to have a proper staff, while but one surgeon has charge of each of the infirmaries of the former. I would ask the county gentlemen—the subscribers and the members of committees of these charities all over Ireland—would not they and the public be gainers if in future, as vacancies occur, a proper staff be elected from the body of medical men of the county town in which these infirmaries are situated? I ask the profession at large, would there not be a better chance for the advancement of the science of surgery, if the practice of these institutions was not confined to one man only, who alone is responsible for his acts, and whose tendency, from the absence of that honourable emulation which characterises the great surgeons of our metropolitan hospitals, must be to relapse into slovenliness and carelessness? I ask you, sir, does not your experience as the conductor of Ireland's Medical Journal, bear me out in what I say?—for I appeal to you, if the literature of our profession has been enriched to the extent it might have been, considering the large field the incumbents of these hospitals have for their labours?

I hope I will not be misunderstood, or supposed to be reflecting in any way upon the abilities of any one of the gentlemen who hold the appointment of County Infirmary Surgeon, of the zeal with which they perform their duties, or of the efficiency of the hospitals under their charge—no one can have a higher respect for the Irish Infirmary Surgeon than I have. I make these remarks merely to suggest a mode by which this efficiency might be increased, more country surgeons made effective—and what I look on as an unfair monopoly removed.—I am, &c.

MUS RUSTICUS.

## LONGFORD WORKHOUSE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Until Dr. Nichols, or some person for him, shows that the official returns which I lately published respecting the comparatively high mortality in the Longford Workhouse, and the comparative paucity of fever patients in it latterly, are incorrect, in any material respect, I shall not notice any observations that are made by that gentleman.

In reference to the resolution of the Board of Guardians, that the remarks which I made “are unfounded and uncalled for,” I would, with great respect to them, observe that if the mortality of their workhouse has been, as I showed from official returns, comparatively high, and if fever patients were disinclined to enter the Workhouse Fever Hospital, my remarks were not “unfounded,” and until they are shown to be “unfounded,” I cannot consider them to be “uncalled for.”

The Poor-Law Commissioners' Reports show that, in the ten years ended September, 1865, the number of fever patients treated in the Longford Workhouse was 631, and that of persons afflicted with other diseases, 4602, and that 541 died in it. Dr. Nichols informs us that not one of these 5233 got a glass of wine, of punch, or of ale, and that not one of the 4061 convalescents got an ounce of meat or a pint of soup! With every possible respect for the Board of Guardians, I am decidedly of opinion that many of the sick and of the convalescents are not

done justice to under such treatment, and have no doubt that, outside the Longford Workhouse, there is not one medical man that differs from that opinion.

DENIS PHELAN.

P.S.—Please to state that 172 in my last letter should have been 1½.

## THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the editorial remarks which appeared under the above head in the last number of your Journal, seem calculated to lead to a misconception, I feel it due to myself to lay the following facts before the profession. Your statement that “*The outgoing Council had been replaced in the administration of the College, although, in addition to the Ex-Councillors, nine Fellows offered themselves to the Fellows for election,*” might lead to the impression that these nine Fellows sought for places on the Council by an attempt to unseat some of the out-going Councillors. On the part of myself, individually, I beg most strongly to disclaim any such intention.

In the unsettled state of the College representation, caused by the lamented and unexpected death of Dr. Banon, it appeared that there would be three or four vacancies on the Council; under these circumstances many valued and influential friends urged me to place my name on the list of candidates, and I do not think I can be accused of egotism if, on reflection, I considered that my standing in the profession as fairly entitled me to such a position as some of those who now enjoy that honour. During the three or four days which intervened between this occurrence and the election, Professor MacNamara withdrew his canvass for the Vice President's chair, and the report of Dr. Mackesy's intended resignation proving unfounded, thus left the probability of two vacancies only. One of these I regarded as vested in Mr. Butcher, should he desire to resume his place in the Council Chamber; still, as one vacancy remained, I felt bound to those who had kindly promised to support me, and accordingly I did not withdraw my name, although fully assured in my own mind that in the present state of parties in the College, I could not hope to be elected. Some zealous friends who knew how matters stood advised me to run against some one of the old members of Council, with a view to make a vacancy for myself, a stratagem which proved so successful at a former election in the College; this I declined to be a party to, as I would not care to accept a seat on the Council obtained by an electioneering manœuvre—which I regard as *undignified—discreditable* to him who resorts to it, and wholly unsuited to such a corporate body as our College of Surgeons. I cannot allow the opportunity to pass without returning my warmest thanks to the large body of independent Fellows who so kindly supported me on that occasion.—I remain very truly, yours,

EDWARD HAMILTON.

120, Stephen's Green, 21st June, 1867!

## WORKHOUSE HOSPITALS IN THE METROPOLIS.

The following are the heads of the new law affecting the management, &c., of the Workhouse Hospitals in the Metropolis:—

*Meetings of the Board.*—Articles 1 to 10. The first meeting is to be held on the 22d of June, at two o'clock, at the office of the Metropolitan Board of Works, to fix the time and place of future sittings. The meetings are to be held once a week at least; seven to be a quorum. The election of a chairman and vice-chairman is provided for, and also the supply of vacancies in those offices. An extraordinary meeting may be summoned at any time on the requisition of two members.

*Proceedings of the Board.*—Articles 11 to 15. Reports on the state of the several asylums are to be read and acted upon; books and accounts relating to relief to be presented and examined; orders on the proper authorities for such sums as may be required; committees may be appointed and powers delegated to them.

*Contracts.*—Articles 16 to 23 provide all the details necessary for the management of contracts and the supply of articles of consumption.

*Orders for Contributions and Payments.*—Articles 24 to 26 provide that every payment greater than £3 shall be made by an order drawn on the treasurer and signed by the chairman and two other managers.

*Appointment of Officers.*—Articles 27 to 30. Every officer is

to be appointed by a majority and reported immediately to the Poor-law Board. Due notice of intended appointments is to be advertised. The clerk and treasurer are to be appointed within sixty days of the first meeting.

*Salaries.*—Articles 31 to 35 provides for the payment of salaries, both regular and exceptional.

*Security.*—Articles 36 to 41. The clerk, treasurer, and other officers to give security.

*Suspension of Officers and Supply of Vacancies.*—Articles 42 to 56 contain provisions upon these subjects.

*Duties of Officers.*—Articles 49 to 52 prescribe in great detail the duties of the clerk and treasurer.

The remaining articles are of little importance.

## Medical News.

**SCIENCE AND ART AT SOUTH KENSINGTON.**—This is, unfortunately, an age of smattering. The so-called intellectual classes, like the Athenians of old, are restless, and always seeking after "some new thing." A stranger, passing through our great city, would see in its south-west quarter, as an apostle once saw in ancient Athens, "an altar to an unknown god"—an altar whereon all that is true and sound in science and art education is being sacrificed to a fatal whim which fosters a miserable craving after superficial knowledge.—*The Laboratory.*

**EXAMINATION IN ARTS.**—During the present week the authorities of the Royal College of Preceptors have been busily engaged conducting the preliminary examinations in Arts, &c., at the College of Surgeons for the Fellowship and Membership of the latter body, and it is stated that nearly 140 candidates have offered themselves.

**DEATH OF M. CIVIALE.**—This celebrated French surgeon died on the 13th instant, almost suddenly, in the 75th year of his age. His writings on the diseases of the urinary organs are universally known, especially on lithotripsy, which he was the first to perform on the living person. All his celebrity was due to hard work, and he continued working until the last, for he was just printing a "Guide for the Operations of Lithotripsy and Lithotomy."

THE presentation of the testimonial to the proprietors of the *Pall-mall Gazette*, which was arranged to come off at Mr. Hill's, 45, Queen Anne-street, Cavendish-square, has been postponed from Tuesday, June 25th, to Wednesday, June 26th, at five o'clock.

A VACANCY for an Assistant-Physician at the Consumption Hospital, Brompton, is about to occur. The election is in the hands of the Committee of Management, and the office may be held in conjunction with another hospital appointment.

DR. WOOD (LL.D.) and Mr. Walter Bagshot, M.A., are the candidates put prominently forward by the Liberal party to represent the University of London in Parliament.

**POISONOUS PILGRIMS.**—It was recently stated by one of our contemporaries that the Hurdwar pilgrims, notwithstanding all the efforts to prevent them, entered the bazaar at Umballa, in India, and had not only infected some of the native population with cholera, but had actually communicated the disease to some of the men of H.M.'s 94th Regiment. A Trieste telegram confirms this intelligence. The cholera still prevails at Umballa, and is, we regret to say, on the increase. The 94th Regiment has lost twenty-one men, and the native population in the surrounding villages is being cut down in large numbers. Surely there is neither principle, policy, nor prudence in the religious toleration which brings us such results as these!

**PHARMACEUTICAL SOCIETY OF GREAT BRITAIN,** June 19th, 1867.—Names of Candidates who passed the Major Examination as Pharmaceutical Chemists—Joseph Bemrose, Liverpool; Charles Eve, London; George Harrison, Sheffield; Edward Jackson Ireland, Egremont, Cumberland; Henry Rayson, Lincoln; Joseph Severs, Leeds; Ralph Walton, Sunderland; Hermann Woolley, Manchester; John Robert Wretts, Ipswich.

**THE QUEEN'S UNIVERSITY IN IRELAND.**—The vexed question as to the validity of the Supplemental Charter, whereby the institution known as the Catholic University, the Magee College, and other educational establishments were affiliated to the Queen's University in Ireland, seems to have been practically set at rest. The original petition filed by certain graduates of the University to nullify the Supplemental Charter was dismissed by the Master of the Rolls on a point of form—viz., that it should have been brought forward as an information by the Attorney-General. His Honour intimated that he agreed with the petitioners on the main question. They were, therefore, encouraged to ask the Attorney-General for his assent to the petition, which having been granted, the case came again before the Rolls Court on the 13th instant. Dr. Ball, counsel for the petitioners, applied for the usual *ad interim* injunction to restrain the Senate of the University from acting upon the Supplemental Charter until the hearing of the suit. Mr. Lawson then rose, and stated that although not instructed to appear on that motion, he had authority to say that the Vice-Chancellor and the members of the Senate would not oppose the suit, as it had been instituted by the Attorney-General in the discharge of his public duty. Under these circumstances, the Court did not consider that it was necessary to issue an injunction, and ordered the motion to stand over until the hearing of the cause. When the matter comes before the Court for final decision, we presume the Master of the Rolls will adhere to the opinion he has already expressed, and decide against the validity of the Charter. The original character of the Queen's University will, therefore, be preserved intact, unless Parliament should think fit to alter it, which is a contingency not to be anticipated.—*Saunders's News Letter.*

**ROYAL COLLEGE OF VETERINARY SURGEONS, LONDON.**—At a special meeting of the Council, convened for the purpose of electing a president, two gentlemen were nominated. Mr. William Field, jun., of Oxford-street, was proposed by the principal veterinary surgeon to the army, Mr. Wilkinson; and Mr. F. Cowie by Professor Spooner. The result of the ballot being declared in favour of the first gentleman, he was declared duly elected, and took office accordingly. Mr. Field, we are informed, is the youngest president of this institution on record.

A WELL-ATTENDED conversazione was given by the professors of University College, London on Wednesday evening last. A selection of vocal and instrumental music, the exhibition of microscopes, and other scientific instruments, in addition to the ordinary attractions of the College, entertained the numerous visitors, among whom were Sir John Lowring and Mr. Bright, M.P., until a late hour.

DR. JORDAN.—This notorious individual has withdrawn the notice of appeal, and paid the penalties inflicted on him by the magistrate at Marlborough-street, amounting to £20 and costs, in the case of the London College of Surgeons and also in that of the Edinburgh College of Physicians. The penalties will go to the General Medical Council, but no doubt will be returned to the respective institutions which so successfully prosecuted the delinquent who so outrages public decency. A writer in the *Pall-mall Gazette* on "How to Deal with Indecent Quacks," states that on receiving one of Jordan's productions, he called on the fellow, returned him his pamphlet, remained with him for a few minutes, and left him apparently suffering from "nervous exhaustion," and recommends other men who are "annoyed by his abominations to pay him a visit after the receipt of the next pamphlet, and leave him in the same abject state."

**SERIOUS, IF TRUE.**—A telegram, published in the *Levant Herald*, conveys the grave intelligence of an outbreak of what is believed to be Asiatic plague at Kerbilah, on the Euphrates. The symptoms seem to point to a modified typhus, but whether this be so or not the malady is certainly a grave one, since it has already carried off 20 per cent. of the population. It has been ascertained to be in part the consequence of the foul miasma following the late floods, and partly the result of the condition of filth and squalor in which the people live. The authorities at Bagdad have taken every precaution to prevent the extension of the pest, and the Galata Board of Health have addressed an urgent request to the Porte that the strictest measures of quarantine may be put in force.

## NOTICES TO CORRESPONDENTS.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor, at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

## BOOKS AND PAMPHLETS RECEIVED.

Report of Committee of the Manchester Statistical Society, on Registration of Deaths.

The Elements of Natural Philosophy. By Charles Brooke, M.A., F.R.S., P.R.M.S. London: John Churchill and Sons.

Hospitals, Infirmarys, and Dispensaries: their construction, management, &c. By F. Oppert, M.D., L.R.C.P.L. London: John Churchill and Sons.

Observations on Medical Education. By Hughes Bennett, M.D. F.R.S.E. Edinburgh: Adam and Charles Black.

The Prescriber's Companion. By Alfred Meadows, M.D. London. Second edition. London: Henry Renshaw, 356, Strand.

Practical Observations on the Harrogate Mineral Waters. By Andrew Scott Myrle, M.D., L.R.C.S.E. London: John Churchill and Sons.

Journal de Médecine for June.

The Mixture Book, including Quack Medicines. By Arnold J. Cooley. London: Hardwicke, Piccadilly.

Introductory Address at the Public Opinion of the Medical Session 1866-67. By W. T. Gardner, M.D.

The Hunterian Oration for 1867. By John Hilton, F.R.S. London: Bell and Daldy, Covent Garden.

The New York Medical Journal for May.

Syphilitic Affections of the Nervous System. By Thomas Reade, M.D., T.C.D., &c.

Germinial Matter and the Contact Theory. By James Morris, M.D. London.

Clinical Lectures on the Diseases of the Skin, Nos. 1 and 2. Illustrated by coloured photographs. By Balmanno Squire, M.B.F.L.S. London: John Churchill and Sons, Burlington-street.

The State of the Medical Profession Further Exemplified. By Edwin Lee, M.D. London: W. J. Johnson, Fleet-street.

The London Surgical Home. By John Scoffern, M.B. Lond.

The Threefold Nature of Health and Disease. By Ed. Haughton, A.B., M.D., M.R.C.S.E.

The Theory of Vital Force Applied to the Cure of Disease. By E. Haughton, A.B., M.D., &c.

Meteorological Observations on the Humidity of the Air of Scarborough. By Cornelius B. Fox, M.D. London: Simpkin, Marshall and Co.

On Pain and other Symptoms connected with the Disease called Hysteria. By Denis De Berdt Hovell, F.R.C.S.E. London: John Churchill and Sons.

## MEDICAL APPOINTMENTS.

ANDERSON, C. L., L.R.C.P. Ed., House-Surgeon to the North Dispensary, Liverpool, has been transferred to the South Dispensary, vice T. Carson, L.R.C.S.I., resigned.

BUCKLEY, Dr., has been appointed Resident House-Surgeon to the North Dispensary, Liverpool, vice C. L. Anderson, L.R.C.P. Ed., transferred to the South Dispensary.

CARTER, A. E., L.R.C.P. Ed., has been appointed Assistant Medical Officer to the Toxeth-park Township Workhouse, Liverpool.

CROCKETT, Mr., has been appointed an Assistant House-Surgeon to the North Dispensary, Liverpool.

FOSTER, Mr. G. F. C., has been appointed Assistant House-Surgeon to the Halifax Infirmary and Dispensary, vice Hoadley, resigned.

KEGO, Mr., has been appointed Assistant House-Surgeon to the South Dispensary, Liverpool, vice D. W. Telford, L.R.C.S. Ed., resigned.

MACHPHERSON, S. H., L.F.P. & S. Glas., L.M., has been appointed Medical Officer for the 1st South-Eastern District of the Freebridge, Lynn Union, vice J. Headley, deceased.

MORGAN, J. E., M.D., M.A., has been appointed Consulting Physician to the Salford Royal Hospital and Dispensary.

OKELL, G., M.R.C.S., L.S.A., has been appointed Certifying Factory Surgeon for the Over and Winsford District, Cheshire.

PATTERSON, Mr., has been appointed an Assistant House-Surgeon to the North Dispensary, Liverpool.

SPANTON, W. D., M.R.C.S.E., has been appointed Medical Officer to the North Staffordshire Infirmary, Etruria, vice G. Barnes, L.R.C.P. Ed., resigned.

BAUMLER, C., M.D., has been appointed a Junior Assistant-Physician to the City of London Hospital for Disease of the Chest, Victoria-park.

RICHARDSON, B. W., M.D., has been appointed Physician to the St. Marylebone General Dispensary, Welbeck-street, vice W. F. Chorley, M.B., resigned.

MACLEAN, A., M.D., has been appointed Surgeon to the Muirkirk Iron Works, Ayrshire, vice S. H. Munro, M.D., appointed Medical Officer to the Nantwich Dispensary and Workhouse of the Nantwich Union, Cheshire.

M'NAB, J., M.D., L.R.C.S. Ed., has been appointed Medical Officer and Public Vaccinator for the Parish of Arsynt, and Physician to his Grace the Duke of Sutherland's Household at Lochinver, Sutherlandshire.

WYLLIE, Dr., has been elected Medical Officer for the Gourrock District. Inverkip, Renfrewshire, vice Dr. Millar, resigned.

MANLEY, Dr., has been elected Medical Officer for the Shankhill Dispensary District of the Belfast Union, vice J. M'Mechan, M.D., deceased.

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

## BIRTHS.

LEACH.—On the 10th inst., at Sturminster Newton, Dorset, the wife of J. Comyns Leach, B.Sc., M.R.C.S., of a son.

EDIS.—On the 13th inst., at Barton-street, Gloucester, the wife of T. Edis, M.R.C.S.E., of a son.

BULLOCK.—On the 13th inst., at Spring-grove, Isleworth, the wife of Henry Bullock, F.R.C.S.E., of a daughter.

ROGERS.—On the 13th inst., the wife of J. Rogers, M.R.C.S.E., of Pagefield House, Swansea, of a son.

MORE.—On the 14th inst., at Rothwell, Northamptonshire, the wife of Dr. More, of a son.

HEWAN.—On the 15th inst., at Minora-street, Eaton-square, the wife of A. Hewan, M.D., of a daughter.

SPUROIS.—On the 15th inst., at Tichmouth Villa, New-road, Hammer-smith, the wife of Frederick W. Spurgin, M.R.C.S., of a daughter.

## MARRIAGE.

MACNAB—SMITH.—On the 13th inst., at Bury St. Edmunds, Robert Macnab, M.D., to Frances Ann, daughter of C. C. Smith, Esq.

## DEATHS.

GRADWELL.—On the 5th inst., at Lytham, Lancashire, W. Gradwell, M.R.C.S., L.R.C.P. Ed., aged 61.

WOOLMER.—On the 6th inst., at Bristol, Shirley E. Woolmer, M.R.C.S., aged 37.

ELLIS.—On the 9th inst., at Brighton, Henry Ellis, M.R.C.S.E., of Rickingham, Suffolk.

JOHNSTON.—On the 11th inst., on Westbourne-park-road, Bayswater, Thomas Glen Johnston, M.D., Surgeon-Major Madras Army, aged 55.

HELM.—On the 15th inst., at Rugby, Mary Elizabeth, wife of George F. Helm, M.A., F.R.C.S., aged 25.

SMITH.—On the 16th inst., at Cromwell-street, Stornoway, John Smith, M.D.

## Advertisements.

## NOTICE TO ADVERTISERS.

## The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under .....	£0 3s. 6d.
Per line afterwards .....	0 0s. 6d.
One-quarter page .....	1 0s. 0d.
Half .....	1 15s. 0d.
One .....	3 0s. 0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the OFFICE, 3, LINCOLN-PLACE, DUBLIN, on MONDAY, by THREE o'Clock.

## INDIAN MEDICAL SERVICE.

INDIA OFFICE, S.W., 12th June, 1867.

NOTICE IS HEREBY GIVEN, that an Examination of Candidates for Twelve Appointments as Assistant-Surgeons in Her Majesty's Indian Medical Service, will be held at Chelsea Hospital, on the 12th August, 1867.

Copies of the regulations for the Examination of Candidates, together with information regarding the Pay and Retiring Allowances of Indian Medical Officers, may be obtained on application at the Military Department, India Office, Westminster, S.W.

T. T. PEARS, Major-General,  
Military Secretary.

LONDON NURSES' INSTITUTE,  
42, South Audley-street, Grosvenor-square, W.

TRAINED NURSES (Medical, Surgical, Mental, and Monthly), can at all times be obtained from this Institute. Hospital Appointments by special arrangement.

Letters and Telegrams should convey the nature of the case to be attended.

Apply to the Manager or Matron.

T. HAMILTON, Manager.

ABSTRACT OF REPORTS

ON THE

LATE EPIDEMIC OF CHOLERA,

AS IT OCCURRED IN THE

Hospitals of Dublin.

---

LAI D BEFORE THE MEETINGS OF THE

Medical Association of the King and Queen's  
College of Physicians, Ireland,

HELD ON THE

27TH OF MARCH AND 4TH OF APRIL, 1867.

# ABSTRACT OF REPORTS ON THE LATE EPIDEMIC OF CHOLERA.

## MEATH HOSPITAL.

### SHORT ABSTRACT OF FACTS CONNECTED WITH THE EPIDEMIC OF CHOLERA.

By GEORGE ROE CARTER,

LATE RESIDENT PUPIL.

(On the part of himself and other Assistants.)

1. *Time occupied.*—The first patient was admitted on the 8th of August into the cholera wards of the Meath Hospital, between which date and the 14th of October, 116 patients were admitted, all of whom were under the supervision of Dr. Hudson. An interval of about six weeks occurred between the closing of the wards on the 20th of October, and opening of the sheds, which were opened on the 1st of December, and closed on the 28th of the same month; during that time fourteen cases were admitted into the sheds, and were treated according to Dr. Stokes' directions.

2. *Accommodation provided.*—The wards of the Meath Hospital for the reception of such cases were first opened under very unfavourable circumstances, which, no doubt, is well known to a great number of the profession, inasmuch as they were quite inadequate in size, situation, ventilation, and other common necessities, which are of such vital importance, not only for the welfare of the patients, but even for the attendants.

The cubic space of the wards are as follows:—

Female ward, 3432 feet; male ward, 4302; they contained six beds each, which only allows 572 cubic feet for each female patient, and 717 for each male, giving an average of 644½ cubic feet for each, without any current of air. The sheds which were erected are in every respect well adapted for the requirements of such patients.

3. *Stage of disease on admission.*—Out of the 116 cases admitted into the above named wards which were treated by Dr. Hudson—five were in the premonitory stage; 108 in collapse or approaching it, and three in consecutive fever; of the 14 cases which were admitted into the sheds and treated by Dr. Stokes, three were in the premonitory stage, nine in collapse or approaching it, and two in consecutive fever.

4. *Mortality at different periods and different ages.*—From the 8th August to the 1st of September the mortality was 48·9 per cent., and from the latter date to the 20th October raised to 54·5 (the increase of which we consider was due to the overcrowding of the wards), and to the condition of the patients on admission, as the earlier cases were more amenable to treatment, while, as the epidemic advanced, the disease assumed a more malignant type, which was probably aggravated by the crowding in our small wards. In December, on opening our large and airy sheds, it went down again to 42·8 per cent., averaging on the whole 51·5 per cent. Over twenty of those patients died within five hours after admission, some in a quarter of an hour, others in from half an hour to two hours. The mortality in children and adults was much under that of the aged, and particularly those whose constitution had been broken down by dissipation, few, if any of them, recovered.

5. *Modes of treatment pursued, varied according to the stage, as follows:—*

(a.) In premonitory diarrhoea and early stage, in two cases castor oil was given, but with discouraging results. Acetate of lead with small quantity of opium, sulphuric acid, and chalk mixture, with kino and catechu succeeded in a number of instances; the vomiting was checked in some cases by freshly prepared charcoal, in a few by bisulphite of soda, but with most effect by creasote and acetic acid, which was subsequently prescribed by Dr. Stokes. We also found a solution of camphor and chloro-

form useful in cramps of the stomach, particularly so when combined with capsicum, and the inhalation of chloroform most effectual in allaying cramps in some bad cases; in addition to those internal remedies, hot stupes of mustard and turpentine were applied, and friction of the surface and extremities with the hands, flannel bandages being applied after friction. Brandy was given freely, and ice *ad libitum*, the latter of which was of much use in allaying thirst and checking vomiting.

(b.) In collapse or approaching it, the patient was enveloped in a blanket wrung out of hot water and mustard, and sprinkled with turpentine, over which a number of dry ones were put, removed when it got cool, and repeated if necessary; this we found to be most efficacious in rousing the patient and raising the temperature of the body, after which mode of packing the radial pulse, which was before it imperceptible, invariably returned, and the patient expressed himself as being much better. We have also tried, with some advantage, Sir Dr. Corrigan's button-shaped cauterium, heated by boiling water and applied over the vagus, and on either side of the spine, which would arouse the patient greatly for the time, though he frequently relapsed into his former condition. In addition to those external applications, calomel and bismuth from gr. ¼ to ½ gr. of the former, to gr. v. of the latter were given every hour, until the secretion of bile and urine was restored; the dose of calomel was subsequently increased (to gr. v. followed by one grain every hour) by Dr. Stokes, also with good results; camphor and chloroform, and the inhalation of chloroform were also employed in this stage of the disease for the relief of cramps. At the suggestion of Dr. White tinct. of canabis indica was extensively tried (in 20 to 30 drop doses) as a stimulant, in some cases with apparent benefit; brandy was freely given also in this stage of the disease. Seven cases were treated by calabar-bean at the request of Dr. Mapother, which Dr. Mapother reported in THE MEDICAL PRESS AND CIRCULAR of the 12th of September; in these seven cases three proved fatal, and with one or two of those who survived we were obliged to discontinue the use of the drug, and put them on calomel, on which treatment they speedily recovered. In some of those cases it produced dysenteric stools, and contraction of the pupil with the cornea slightly injected. (As the number of cases treated by the drug were insufficient to test its value in this disease, we cannot either condemn or recommend its use, but we are of opinion that the results from its more extensive trial would not have been so favourable as those of the calomel treatment). Two cases were treated by Dr. Stokes, by the injection of salines into the veins which proved fatal, (but as they were previously treated by calomel, and the number not sufficient to test its value, we cannot say anything in favour of it or otherwise).

*Stage of suppression of urine, and consecutive fever.*—  
(c.) For suppression of urine the patient was cupped over the lumbar region, and 3 or 4 ⅓ removed, after which a hot bran poultice was applied to the foot, and diuretics administered. In several instances the cupping was repeated with great advantage, and we have succeeded (in bringing on the flow of urine in a good many cases, when complete suppression of that secretion had existed for over 48 hours, and even from patients who were far advanced in uremia) by those measures; calomel and bismuth was also given in this stage of the disease as before, but stimulants were not administered so freely. In the consecutive fever, if the evacuations from the bowels were bilious and copious, the calomel was either discontinued altogether or given in small doses at long intervals; if the pulse was strong and regular, tongue moist and rather clean, no gastric irritation or delirium, the patient got a moderate quantity of brandy or wine, chicken broth or weak beef-tea, bread and milk or tea and ice *ad libitum*. In the advanced stage of uremia,

when head symptoms were present, the characteristic odour from the patient with complete suppression of urine, we have seen the best results follow, repeated cupping over the loins with the administration of diuretics, the shaving of the head and blistering the nape of the neck, and from the application of leeches to each mastoid process, with a calomel and rhubarb purge when there was no motion of the bowels for a few days. Such were the modes of treatment adopted during the late epidemic by Dr. Stokes and Hudson, and if time or space would admit, we could bring forward a number of important cases which were successfully treated. During the whole epidemic only two cases occurred in the hospital, which was in the interval when no cholera cases were in the wards, or had been for ten days previous. One of those patients was convalescent from typhoid, and died in nine hours illness, the other was in the thirteenth day of typhus, with high nervous symptoms, and died in about twelve hours illness. The night nurse and washerwoman attending on the cholera wards were attacked; the former made a wonderful recovery, but the latter died in less than twenty-four hours illness. We also had a case associated with pregnancy, who was admitted in a very precarious state, the woman was six months pregnant. The treatment as in other cases was adopted, and the patient left hospital perfectly well, without any sign of abortion.

HOUSE OF INDUSTRY HOSPITAL.

SUMMARY REPORT ON THE CASES OF CHOLERA ADMITTED TO THE HARDWICKE HOSPITAL 1866.

Collected by Mr. J. ADAMS CLARKE, Clinical Clerk.

Edited by Dr. LYONS.

DURING this epidemic, a total of 277 cases were admitted into the cholera wards, and no case of cholera was refused admission; several were admitted which had failed to procure admission elsewhere. From these cases were rigidly excluded, by the Clinical Physicians, all instances of vomiting and purging, with or without cramps, which did not strictly correspond to the type of true Asiatic cholera. There were thus recorded of

True cholera	. 193 cases, of whom 128 died.
Diarrhœa	. 68 " " " " 1 "
Vomiting and cramps	16 " " " " None "
	277                      129

Of diarrhœa, including choleraic diarrhœa, 68 cases were admitted, of which the first was taken in on June 25th, and the last on December 3rd. Occurring during the prevalence of a cholera epidemic, these cases, it is highly probable, belonged to the epidemic constitution then prevailing; only 1 case proved fatal. It occurred in the person of a man, aged 45, who was admitted on the 6th of August, and died on the 10th. Prior to the 25th June no case of diarrhœa had been admitted into the Hardwicke Hospital for a period of six months.

Cholera.—Of undoubted cases of true cholera 193 were admitted, of whom 128 died. The first case occurred in the person of a girl aged 7 (Susan Carleton), who was admitted on the 22nd of August; she had lived in Church-street, 127; she died on the 23rd of August. The last case of death from cholera occurred on the 5th December, 1866; but the last case of cholera disposed of in hospital was discharged cured on the 28th December, 1866.

Subjoined is a tabular view of the duration of the fatal cases in hours prior to their admission to hospital:—

Admitted Dead.	FATAL CASES—DURATION OF DISEASE BEFORE ADMISSION TO HOSPITAL.											
	Under 1 hour.	Under 2 hours.	Under 3 hours.	Under 6 hours.	Under 12 hours.	Under 24 hours.	Under 48 hours.	Under 72 hours.	Under 96 hours.	Under 5 days.	Under 5 days.	Not known.
1	2	3	3	16	38	22	12	5	7	5	3	6

The following table exhibits the actual number of cholera cases by sexes and ages:—

ADMISSIONS BY AGES.	Under						Over	Total	Deaths.
	5	10	20	40	50	60	60		
Males...	7	9	17	26	11	3	7	80	48
Females	6	9	19	41	12	13	13	113	80
Totals	13	18	36	67	23	16	20	193	128

Last case discharged cured 28th December, 1866.

The largest number of admissions occurred during week ending 27th October—11 males, 12 females; total, 23.

The largest number of deaths during the same week (27th Oct.)—4 males, 11 females; total, 15.

The geographical distribution of the above cases was as follows:—

From N. side of Dublin,	85, i.e., north of the Liffey.
From S. " " "	105, i.e., south of the Liffey.
From Arklow, Wicklow,	
(Dublin Bay),	1
From Kingstown, co. Dublin,	1
From Westport, co. Mayo	1 (Guard in M. G. W. Railway got ill on way).
Total,	193

The admissions per month were as follows:—

	July.	Aug.	Sept.	Oct.	Nov.	Dec.
Males ...	1	10 <sub>8</sub>	21 <sub>14</sub>	24 <sub>15</sub>	21 <sub>13</sub>	3 <sub>1</sub>
Females...		11 <sub>6</sub>	24 <sub>14</sub>	39 <sub>29</sub>	33 <sub>24</sub>	6 <sub>4</sub>
Totals...	1	21 <sub>(14)</sub>	45 <sub>(28)</sub>	63 <sub>(44)</sub>	54 <sub>(37)</sub>	9 <sub>(5)</sub>
				Total, 193.	(Deaths, 128.)	

N.B.—The small figures indicate the deaths.

Diarrhœa, including choleraic diarrhœa—Total, 68, including 1 death.

First case admitted June 25th.

Last " " Dec. 3rd.

The next table exhibits the mortality for sexes and ages respectively:—

DEATHS FOR AGES	Under						Over	Total.
	5	10	20	40	50	60	60	
Males ...	4	6	8	15	10	2	7	52
Females	4	7	7	25	11	10	12	76

The excessive mortality of females of the ages of 40, 60, and upwards at once strikes the eye.

In the subjoined table will be found the percentage mortality of the sexes, ages, and for the months of the epidemic:—

TABLE OF PERCENTAGE MORTALITY.

The percentage mortality in the total of true cholera cases was	...	} 66·3 per cent.
For males the mortality was	...	
For females " " "	...	

FOR THE SEVERAL MONTHS THE PERCENTAGE MORTALITY WAS:

Aug.	Sept.	Oct.	Nov.	Dec.
66·6	62·2	69·84	68·5	55·5

FOR THE SEVERAL AGES AND SEXES THE PERCENTAGE MORTALITY WAS:

DEATHS FOR AGES	Under						Over.
	5	10	20	40	50	60	60
Males	57·14	66·6	47·	57·69	90·9	66·6	100·
Females	66·6	77·8	36·4	60·9	91·66	76·9	92·3

The next Summary shews the duration in hours of the fatal cases in Hospital:—

FATAL CASES—DURATION OF DISEASE IN HOSPITAL.

Brought in dead.	Under 1 hour	Under 2 hours	Under 3 hours	Under 6 hours	Under 12 hours	Under 24 hours	Under 36 hours	Under 48 hours	Under 72 hours	Under 96 hours	Under 10 days
1	1	2	2	6	28	50	3	13	7	4	10
90 died within 24 hours.						16 died within 48 hours.					
Total 128 deaths.											

We annex a summary of the results of various plans of Treatment by:—

	Deaths.	Recoveries.
Emetics ...	—	—
Purgatives ...	—	2
Astringents { lead and opium catechu, &c. chalk, &c.	15	18
Calomel ...	31	16
By stimulants { chl. ether, sp. am. brandy, &c.	40	13
Without stimulants ...	—	1
By special treatment as white of egg ...	8	2
Calabar bean ...	—	1
Camphor and chloroform	11	3
Camphor, capsicum, and creasote	8	4
Warm bath ...	—	1
With milk ...	—	—
Diuretics ...	—	1
No entry ...	13	13
Permanganate of potash	1	—
Ice, brandy, &c. ...	1	—
<b>Total</b>	<b>128</b>	<b>75</b>

These persons were exposed to the full influence of the disease, of whom 2 only exhibited it, and 1 of whom only died.

The cholera wards of the Hardwicke Hospital are two of the ordinary fever wards; they are under the same roof as the other wards, and all the wards open upon a common well-stair-case and central hall, and it is impossible to conceive that in changing and varying winds admixture of the atmosphere of the cholera wards with that of the other wards did not frequently take place.

The fever wards were occupied by ordinary cases during the cholera period to the total number of 428; of these five patients only exhibited cholera.

I. FEVER PATIENTS IN HARDWICKE DURING CHOLERA EPIDEMIC, FROM JULY 26TH TO DECEMBER 16TH, 1866.

July 26th to 31st	10 patients.
August 1st to 31st	92
Sept. 1st to 30th	81
Oct. 1st to 31st	107
Nov. 1st to 30th	67
Dec. 1st to 28th*	71

Total 428 patients.

This total number of 428 includes simple typhus and typhoid fever, small-pox, scarlatina, and measles.

II. FEVER PATIENTS WHO TOOK CHOLERA IN THE HOUSE.

- Edward Corcoran, admitted with fever 26th July; got cholera August 30, 1866.
- Thomas Berry, admitted with fever 28th August; got cholera.
- Ellen Brennan, admitted with fever 9th October; got cholera.
- Mary McMahan, admitted with fever 10th October; got cholera.
- Margaret Leary, admitted with fever 20th October; got cholera.

Died.

Summary.—Total fever, &c., cases in Hardwicke during the period commencing July 26, and ending December 28 . . . . . 428

Total number of these cases that took cholera during this period . . . . . 5

It will thus be seen that of a total of 60 persons in the establishment, and 428 patients in the Institution, in all 488, only 7 exhibited cholera, being in the proportion of 1.43 per cent.

Five cases of cerebro-spinal arachnitis occurred in the sequela of cholera. In no single case was true cholera typhoid developed as a sequel of cholera.

\* The last cholera patient was discharged cured December 23, 1866.

MOUNTJOY MALE GOVERNMENT PRISON.

REPORT ON THE CHOLERA OUTBREAK AT THE CLOSE OF THE YEAR 1866.

A DETAILED account of the circumstances connected with this outbreak will, I conceive, have considerable interest in the eyes of medical men.

The following is a brief summary of the post-mortem appearances:—

General Summary of Post-mortem Appearances.

- Body generally—Rigor well-marked; lividity diminished; temperature raised, as compared with that before death.
- Brain—Healthy.
- Spinal chord—Healthy.
- Ganglionic centres (solar plexus and semilunar ganglia)—Healthy.
- Blood—Thick and tarry.
- Heart—Right chambers loaded; pulmonary artery contained coagulum.
- Lungs—Occasional congestion; no constant condition.
- Stomach—A washed appearance; but varied with ingesta, taken in before death.
- Intestines—A general washed appearance; pale pink colour; sago-grain appearance of minute glands.
- Liver—No marked appearance noticeable.
- Spleen—No special characters.
- Kidneys—Rather bloodless; and in cases of prolonged life with uræmia, some congestion with infarction of tubules.

There were 26 persons, 4 males, and 22 females employed in the Hardwicke Hospital during the cholera period; 4 nurses and 2 ward-maids were in constant attendance on the cholera patients; all the others were in close proximity and frequently assisted in carrying in patients, &c.; 5, exclusive of the laundry-superintendent, were constantly engaged in washing the clothes of the cholera patients; of all them but 1, a laundry-maid, took cholera, and she died of it. She was some hours ill with cholera in the sleeping room of the laundry-maids, who were all in close attendance upon her; 4 physicians, 4 clinical clerks, 2 temporary do., and a class averaging 20 per day were in daily attendance; 1 clinical clerk (Mr. Henry) exhibited cholera, but recovered. In all—4 physicians; 4 clinical clerks; 3 temporary do.; 1 steward and paymaster; 1 registrar and accountant; 20 pupils (at a minimum); 26 domestics and superintendents; 1 diet clerk;—Total 60.

The facts have a scientific value on account of the neatness, precision, and accuracy with which they can be ascertained within the walls of such an institution as a prison. Let me state, that I do not myself advocate any theory on the subject of the propagation of malignant cholera. I do not doubt that the disease is capable of being communicated from the sick to the healthy; but it appears to be equally certain that there are cases where malignant cholera cannot be logically traced to this origin. I shall confine myself to a simple statement of facts.

The Mountjoy Prison stands in a salubrious situation. Since it was opened for the reception of prisoners in the year 1850, the health of the convicts received into it has been such as to contrast favourably with other similar institutions. There has never been any prevalence of diseases such as arise from imperfect sewerage; it is built on a heavy blue clay soil, and on a sloping ground, so that within the prison walls there is a fall of twenty feet from the upper to the lower part. There is a well of water (not used for the supply of the prison) about the centre of the grounds; this well is ninety-five feet deep, and the water is tolerably strongly chalybeate. The prison is built upon what is known as the Pentonville plan, that is four arms radiating from a centre. Each of these arms is known as a division (A, B, C, D divisions), and consists of corridors with cells on each side. There are three tiers of cells, one over the other. There are basement stories under each division except A. These basements contain store-rooms and work-shops, but no cells. Each cell contains a little over eight hundred cubic feet of space, and there is an arrangement for ventilation (independently of the window), similar to that in Pentonville prison, where it is calculated that the air is renewed at the rate of about two thousand cubic feet per hour.

There is water-closet in every cell, well trapped and supplied with an abundance of water. At the lowest extreme of the prison grounds there are three large underground sewage tanks in which the more solid part of the sewage accumulates, and is used from time to time as manure; the liquid sewage flows off by a large sewer.

The canal of the north side of the city of Dublin has two branches in the angle between which the prison stands, the water in these branches is on a higher level than the ground on which the prison is built.

During the early part of December, 1866, the health of the prisoners was as good as it had been at any time for ten years before. On Saturday, December 22nd, 1866, there were 288 prisoners in the prison, (145 convicts, and 143 untried political prisoners), there were only five sick in hospital. On the forenoon of Sunday the 23rd December, five cases of malignant cholera occurred, of which three died before many hours. On the 26th two other cases were admitted to hospital, and on the 27th two more—of these one died; no case has occurred since then. In all there were nine cases of malignant cholera, of which four died. Upon the day following the first appearance of cholera, sixty-four cases of diarrhoea were reported,\* and placed under treatment—twenty-one convicts, forty-three among the untried political prisoners.

As to the introduction of this disease from without by the warders or prison officers, the following are the facts:—

No one of the warders or other officers had had cholera, neither had there existed any cholera among their families.

Mr. Ward the resident apothecary had not seen any case of cholera for years. I had not myself been in contact with a case of cholera since the beginning of October (nearly three months before.)

\* Immediately on the first appearance of the disease each warder in the prison was directed to go round each prisoner in his charge, and enquire whether he was suffering from any bowel attack; 64 cases were returned by the warders, and at once placed under treatment.

The outbreak commenced and terminated within a week. The nine cases of cholera all presented symptoms of collapse; in one case only were the cramps severe, in all there was the usual vomiting, purging, cold-blue extremities, husky voice, sunken eye, thirst, cold tongue and breath, &c.

The prisoners attacked were not in communication with each other, or with the same warders. In short, I have been wholly unable to trace this outbreak to any communication between the sick and healthy. None of the warders, officers, or prisoners who were in attendance on those ill of cholera took the disease. It has been surmised that the disease may have been propagated from the Mater Miserecordiæ Hospital, which is distant from the prison some 300 paces. I have learnt that there was no case of cholera in this Hospital at the time that the disease broke out in the Mountjoy Prison; the last case admitted to that hospital was taken in on December 17th, and died on the 18th; for ten days before that there had been no case of cholera in this hospital.

*Water Supply.*—The water used in the prison is drawn from the reservoir from which the north side of the City of Dublin is supplied, it is conducted through iron pipes, and passing through a filter of gravel is received in a large supply tank placed at the highest part of the prison ground, remote from, and about twenty feet higher than the sewage tanks. From the supply-tank it is pumped by engine to the cistern on the top of the prison. As it enters the supply tank rather slowly through the filtering apparatus, it happens that the engine pumps it out more rapidly than the water flows in. The result is that at about four o'clock every day, the supply-tank is pumped nearly empty, and thus every twenty-four hours there is an entirely fresh supply of water drawn.

The female prison adjoining is supplied by water from the same tank, no case of cholera occurred in the female prison. I examined the water and have found it limpid and colourless. It is a water of as good quality as any supplied on the north side of Dublin; it is pleasant to drink, free from odour or taste, sufficiently soft and containing some saline matter, (magnesia and lime).

*Food and Dietary.*—The bread, soup, milk, oatmeal, stirabout, &c., used in the prison appears to me to be of good quality; the steward and cook inform me that they consider the food supplied during the month of December of good average quality. The beef used for the soup, &c., is supplied at the contract price of 5½d. per pound (exclusive of bone), mutton 8d. per pound (not exclusive of bone). Bread 2-6 pence per two pound loaf.

The cooking is performed by a steam apparatus, and is carried on in large cast iron boilers kept scrupulously clean.

The untried political prisoners are permitted to get their own food sent in by their friends if they please; some half dozen only availed themselves of this privilege: one of those (who was not making use of any of the prison food at all) was among those attacked with bad choleraic diarrhoea.

Among the other prisoners two distinct dietaries were in use, as follows:—

DIET ON SATURDAY, DECEMBER 22ND, 1866.

	Untried prisoners and working convicts.	Convicts of probationary class.
Breakfast . . .	bread and coffee,	stirabout and milk.
Dinner . . .	½lb. beef, broth and 2lbs. of potatoes,	bread and milk.
Supper . . .	bread and milk,	bread and milk.

Cholera appeared simultaneously among the persons on these distinct scales of diet. As some have supposed that the milk was the special article of diet at fault, I have examined carefully into the circumstances concerning it. The milk supplied by the predecessor of the present contractor was of bad quality, it was supplied at the low figure 5½d. per gallon, it was frequently rejected, and finally the contract was broken. On September 6th, the milk contract was transferred to other hands at 10½d. per gallon. Since then the milk supplied has been of good quality, (it was, however, on one occasion rejected October 5th, 1866).

I have frequently examined the milk, and have never found it to be adulterated with anything except water. The maximum of added water amounts to not more than 25 per cent: (usually much less than this) a dilution which, I do not consider warrants the rejection of milk, inasmuch

as the milk generally supplied throughout Dublin in private families is diluted to about this degree. In justice to the individual who at present supplies milk to this prison, (and of whom I may add, I know nothing), I feel bound to state that in my opinion the article furnished by him is good average milk.

Several of the Prison Officers from choice make use of this milk; from them I learn that they have had no fault to find with it—one of the prisoners who died of cholera had taken no milk the day before he was attacked, save the small quantity in his coffee which had been boiled.

Cases of cholera occurred in each wing of the prison, no wing escaped; with one exception all those taken ill of cholera were in the upper stories, four were in the highest story, four on the second, and one below.

I examined the closets in the cells which had been occupied by each case, and found that all were in good order.

None of the prisoners attacked had been under the depressing influence of any special punishment by curtailed diet or otherwise.

The prison faces south-west, and the Mater Misericordiæ Hospital stands 300 paces in front (that is south-west) of it. During the days which the cholera lasted, the wind blew from the south-west almost continually. On the night of the first appearance of the disease, the atmosphere was fully saturated with moisture—the wet and dry bulb thermometers stood equal. I subjoin a table giving some particulars concerning the individuals attacked. Happily the efforts made to prevent the spread of the disease were eminently successful.

Infected clothes were burned, incipient cases promptly attended to, and every part of the Prison and Hospital disinfected with carbolic acid and solution of sulphate of iron, which were thrown into the closets and sewers.

TABLE OF CASES ATTACKED WITH ASIATIC CHOLERA DURING THE LAST WEEK OF DECEMBER, 1866.

Name of Prisoner.	Reg. No.	Date of reception in this prison.	Place whence he came.	How long in the cell in which his illness commenced.	How long in this prison.	Number of cell and corridor.	Whether premonitory diarrhoea existed, and how long?	Date of admission to hospital.	Termination of Case.
John K. ...	7238	Ap. 27, 1866	Lifford Gaol, co. Donegal	Nearly 8 months	8 months	C 2, 7 cell	No premonitory diarrhoea.	Dec. 23, 1866	Death at 10 that night.
Wm. M. ...	Untried	Sept. 1, 1866	Kilmainham Gaol	1 mth. & 27 days	4 "	A 2, 13 "	No premonitory diarrhoea.	" " "	Death at 6 that eve.
J.M.C. ...	7255	July 9, 1866	Monaghan Gaol	2 mths. & 11 days	5 "	C 3, 37 "	Had diarrhoea for 48 hours.	" " "	Death at 12 next day.
G. T. ...	6987	May 12, 1866	Spike Island Prison	4 months nearly	7 "	D 3, 45 "	Violent vomiting was the 1st symptom.	" " "	Recovery.
*J. H. C. ...	7045	July 13, 1866	Londonderry Gaol	12 days	5 "	D 2, 41 "	Diarrhoea during night of 22nd.	" " "	Recovery.
J. S. ...	7229	Ap. 12, 1866	Spike Island Prison	About 8½ months	8 "	D 2, 40 "	Diarrhoea on the 24th, not checked by treatment.	" 26, "	Recovery.
+A. L. ...	7230	Ap. 17, 1866	Richmond Bridewell	About 1½ months	8 "	C 3, 32 "	1st symptoms violent vomiting and purging.	" " "	Recovery.
John M. ...	7100	Nov. 4, 1865	Maryboro' Gaol	5 mths. & 20 days	13 "	D 1, 23 "	Collapse from the first, no premonitory diarrhoea.	" 27, "	Death at 11 on night of 28th.
‡T. N. ...	Untried	Dec. 18, 1866	Clonmel Gaol	About 8 days	8 days	B 3, 18 "	Premonitory diarrhoea came on on the 25th; treatment did not check it, and vomiting supervened.	" " "	Recover.

\* During convalescence this patient was covered with a rash resembling measles.

† This patient was for 24 hours apparently hopelessly collapsed.

‡ This man had never, to his knowledge, been in contact with cholera. There had been no cholera in Clonmel for three months before his committal.

§ A. B. C. and D. indicate the wings of the prison radiating from a centre; 1 indicates the lowest story; 2 the second; and 3 the top. No case of cholera had occurred among any of the prison officers or their families. The outbreak terminated within one week from its first appearance. There were 64 cases of diarrhoea reported on the first day of the outbreak; some of these were severe, and were attended with vomiting, but none are put down in this table save those who were in collapse.

SIR P. DUN'S HOSPITAL.

SUMMARY OF CHOLERA REPORT.

By E. W. COLLINS, A.B.  
RESIDENT MEDICAL SCHOLAR.

ELIZABETH MEYLER, in a short time after the death of her husband from cholera, sickened, and was brought to Sir P. Dun's Hospital (Aug. 2nd, eleven A.M.) twenty-four hours and a half after being attacked, and died sixty-three hours and a half after admission, after an illness of eighty-eight hours.

This was the first case which sought admission into Sir P. Dun's Hospital.

There were in all 180 cases of cholera treated in this hospital, dating from August 2nd, 1866. Of these 180 cases, the particulars of 148 are as follows:—

Symptoms, &c., in 148 cases.	Number of patients thus affected.	Percentage of patients thus affected.	Number of patients not thus affected.	Percentage of patients not thus affected.
Purging ...	142	95·94	6	4·06
Vomiting ...	130	87·83	18	12·17
Cramps ...	84	56·75	64	43·25
Collapsed on admission ...	74	50·	74	50·

Of these 148 cases 72 (48·64 per cent.) belonged to the male, and 76 (51·36 per cent.) to the female sex; 70 (47·29 per cent.) died, and 78 (52·71 per cent.) recovered. The average length of time which elapsed between the commencement of the illness of each of these cases, and their admission into hospital was 48·35 hours. Moreover, the entire duration of the disease in the cases of those who succumbed was, on an average, 79·34 hours. In other words, these patients lived, on an average, only 31 hours after they came into hospital. The order of constancy of the symptoms was, as may be seen, purging, vomiting, and cramps, the coefficients per cent. of each of these symptoms, respectively, being 95·94, 87·83, and 50·75. Diarrhoea, therefore, was all but uniformly present. Of the few cases, altogether six in number, in which it did not occur, 50 per cent died, and it may be mentioned as a singular fact, that all save one belonged to the female sex. Five out of the six had vomiting and cramps, and two were collapsed on admission. One suffered only from cramps, and she died, her illness proving fatal in six hours: when taken out of the cholera-van she was found to be dead. Another, a boy, æt. 6, who only laboured under vomiting, gradually exhibited the symptoms and signs of tubercular meningitis with effusion, of which he died 408 hours after admission; the autopsy verified the

diagnosis. The details of these cases which were characterised by absence of the most constant of all the symptoms of cholera are subjoined:—

TABLE CONTAINING THE DETAILS OF THE CASES IN WHICH THERE WAS ABSENCE OF PURGING.

Cases in which no diarrhoea occurred.	Vomiting.	Cramps.	Collapsed.	Length of illness in hours before admission.	Recovered.	Deaths.	Period in hours of death after admission.	Females.	Males.	Agcs.

6th	1	1	...	24	1	...	...	1	...	40
TOTAL	...	5	5	2	...	3	3	...	5	1

Of the effect of mental emotions as predisposing causes, in the production of cholera, the following is a remarkable instance:—

Eliza Singleton, *æt.* 25, a fruit-seller, sold some apples from her stall to a woman who was one of her usual customers. In a few hours after a funeral passed by, which, on enquiry, she learned was that of the woman to whom she had sold the fruit in the morning, and that she had died of cholera. Such was the effect produced by this intelligence, that on the moment she took ill, and had to be removed to her home. Purging, vomiting, and cramps set in, and were rapidly followed by collapse. When brought to the hospital she was in a state of profound collapse, out of which she happened to be amongst the few who recovered. In another instance, a boy, aged five years, was admitted, labouring under an extraordinary presentiment that he should contract and should die of cholera, in consequence of the death of a playmate in the same house from the disease.

This child died, the disease running its fatal course in 23 hours. In two cases the commencement of the disease dated from the time of administration of a dose of *ol. ricini*. Errors of diet in a vast number of instances appear to be the predisposing causes. In a few rare cases, 5 in number, no vomiting or purging occurred during the stage of collapse, in which they were admitted, these cases all died. As a rule, the cramps attacked the muscles of the upper less frequently than those of the lower extremities. Still less frequently those of the abdomen were engaged. A great number of the cases admitted, suffered from suppression of urine in a greater or less degree. Coma was very frequently the precursor of death in the cases of suppression of urine, unaccompanied by any of the other signs of uramic poisoning. One of these patients secreted no urine for 3 days. But the most extraordinary case of recovery with this complication was that of a man named Maguire, aged 40, who suffered from suppression 72 hours. Another case (that of John Arthur, *æt.* 30), in which, according to the patient's own account, suppression had lasted for a corresponding period, was not attended with an equally favourable issue, death following at the close of the 4th day. In the case of a man, aged 39, suppression still continuing at the end of the 3rd day, blood to the amount of 4 ounces was taken from the arm, and in half an hour after he secreted and passed some urine. In another instance, however, though for the same complication, venesection was ineffectually tried. After suppression had existed for 60 hours, in another case dry cupping over the loins was tried, and 12 hours after the secretion returned. The cadaveric twitchings which occurred in

several instances are worthy of special notice. The case of a boy named Villiers, aged 10, may be more particularly alluded to. In this instance about 5 minutes after breathing had ceased, and all other signs of animation had departed, slight tremulous spasmodic twitchings and quivering of the muscles were observed, especially of those on the inside of the thighs, legs, and feet, (so much so, indeed, that inversion, eversion, flexion, and extension were frequently performed, and the left foot was at one time raised about 3 inches from the bed on which it had been lying), of the abdominal, the pectorals, and of the muscles of the forearms and of the hands. These cadaveric movements shortly after death were also very remarkable in the case of a woman, Emma Louisa Consen: about 20 minutes after death, the muscles of all her toes, the same set of muscles which had been especially, during life, the seat of the cramps, were seen sometimes all together, sometimes one by one, to contract and relax. The patella also was frequently drawn up by the quadriceps extensor. The muscles of the abdomen visibly quivered and contracted. The blood was found to be of a thick black, and tarry consistence.

The general line of treatment adopted was to arrest the diarrhoea and vomiting as soon as was possible, by the administration of astringents and sedatives. For these purposes acetate of lead and opium were exhibited. In cases where these remedies failed to moderate the diarrhoea injections of acetate of lead and opium, to the extent of fifteen grains of the former with half a drachm of the acetons tincture of opium, were employed generally with marked effects. Dr. Kennedy's patients immediately after their admission got a mustard emetic. Where vomiting was the prominent symptom, Hydrocyanic acid (dilute) in variable amount to the extent of seven drops was exhibited singly, or in combination with Schacht's solution of bismuth. For the same purpose acetate of lead, spearmint water, sinapisms to the epigastrium, and mustard emetics were employed. To relieve the cramps manual friction, chloroform inhalations, turpentine stupes, sinapisms, and in some cases immediate blistering, were the means adopted. It was in those cases in which the cramps were unusually severe that chloroform inhalations appeared to be attended with the best results. In and previous to the stage of collapse stimulation was resorted to, both externally and internally. Externally by sponging with powerfully stimulating liniments of compound camphor liniment and chloroform, by the employment of manual friction, by dry heat, (by means of hot jars and heated sand), and by swathing the body and limbs in flannel. Internally by the exhibition of brandy, wine, mustard emetics (Kennedy), and camphor and chloroform in solution (Banks). When suppression of urine supervened this was combated by hot stupes of turpentine to the hypogastric region, by dry and wet cupping over the loins, and in some rare cases by venesection. In some cases, though urine was secreted, it was retained in the bladder; in these cases the catheter afforded relief. The solution of the permanganate of potash was given internally by Dr. Moore in a few instances, but its use was soon discontinued. Calomel also was similarly tried by Dr. Kennedy with little efficacy.

The mortality among the patients bore a direct proportion to the length of time they lasted after admission. Thus, amongst those who came into the Hospital, the greatest mortality occurred within the twelve hours succeeding the admission, 21 per cent, or one-fifth of all the patients admitted having died within that time. More than one-third (37.57 per cent.) died within 36 hours, somewhat less than one-third (31.21 per cent.) within 24 hours, and, as before stated, one-fifth (21.02 per cent.) within 12 hours after admission; one-fifth (21.02 per cent.) died between the 1st and the 12th hours (inclusive), one-tenth (10.19 per cent.) between the 13th and the 24th (inclusive), and one-sixteenth (6.36 per cent.) between the 25th and the 36th hours subsequent to admission. The following is a return, in a statistical form, of those cases—58 in all— which died 36 hours after admission:—

Hours after admission (inclusive).	Deaths.	Per centage of deaths, in relation to the total number of deaths (72).	Per centage of deaths, in relation to the total number of cases admitted (157).
12	33	45·83	21·02
24	49	68·05	31·21
36	58	80·55	37·57
Between 1st and 12th	33	45·83	21·02
„ 13th and 24th	16	22·22	10·19
„ 25th and 36th	9	12·50	6·36

The particulars of these cases are subjoined:—

Totals...	30	16	12	26	32

It will be seen from the foregoing table that, of those who died within 36 hours after admission, an unusually large number fell to the lot of Dr. Moore, a fact which accounts for the high coefficient of mortality (50 per cent.) of the patients who came under his charge.

It has been stated that the greatest mortality in cholera occurs at the extremes of life, among the very old and the very young. The truth of this may be tested by the following return of the cases between the ages of 1 and 79 (inclusive):—

Ages (inclusive.)	Recovered.	Died.	Males.	Females.	Total number of cases.	Per centage of deaths amongst those attacked.
1 to 9	17	12	16	13	29	41·33
10 „ 19	17	10	14	13	27	37·03
20 „ 29	18	13	14	17	31	41·93

50 „ 59	4	3	3	7	10	60·
60 „ 69	2	4	2	4	6	66·66
70 „ 79	1	...	1	...	1	.....
TOTAL...	75	70	71	74	145	48·27

The return shows that, of the patients admitted into Sir P. Dun's Hospital, the greatest mortality occurred amongst those between the ages of 60 and 69, and 40 and 49 inclusive, the best amongst those between the ages of 10 and 19 and 1 and 9 respectively (inclusive). The epidemic spared neither age nor sex. The mortality amongst each sex was almost alike; each was alike obnoxious to the poison.

Sex.	Died.	Recovered.	Total number admitted.	Percentage of those who died.	Percentage of those who recovered.	Percentage of the total number of cases admitted.
Females	44	50	94	51·76	52·63	52·22
Males	41	45	86	48·24	47·37	47·78
Total...	85	95	180	100	100	100

Of 180 cases admitted into this hospital, 94 (52·22 per cent.) belonged to the female, and 86 (47·78 per cent.) to the male sex. Of the former 44 (51·76 per cent.) died, and 50 (52·63 per cent.) recovered. Of the latter 41 (48·24 per cent.) died, and 45 (47·37 per cent.) recovered. Thus the coefficients of mortality of the sexes only differed in the trifling sum of 3·52 per cent.

Again, if the time during which the epidemic of cholera prevailed—from August 2nd, 1866, to January 1st, 1867 (inclusive)—be divided into five periods of a month each, the coefficients of mortality for each of these periods in their order, and finally, the total coefficient of mortality of the patients admitted into this hospital, will be found in the annexed table.

The coefficients of mortality:—

Monthly periods.	Admission.	Deaths.	Recoveries.	Coefficients of mortality per cent.
First, (August 2nd to Sept. 1st).	22	12	10	54·54
Second, (Sept. 2nd to Oct. 1st).	51	25	26	49·01
Third, (Oct. 2nd to Nov. 1st).	77	35	42	45·45
Fourth, (Nov. 2nd to Dec. 1st).	27	13	14	48·14
Fifth, (Dec. 2nd to Jan. 1st).	3	...	3	...
Total...	180	85	95	47·22

From this table it may be seen, as has been elsewhere observed, that the earliest cases of cholera were by far the most fatal. The coefficients of mortality steadily decreased during the 1st, 2nd, and 3rd monthly periods, but rose again upon the 4th to almost the same rate as during the 2nd.

The general line of treatment adopted by each of the physicians who had charge of the hospital during the prevalence of the epidemic was practically almost the same. It would, therefore, be predicated that there would be little variation in the coefficients of mortality of the patients under each, and such, indeed, was the fact. For, the high rate of mortality amongst the patients of Dr. Moore may be fairly attributed to the large proportion of the rapidly fatal cases which came under his charge. And, with regard to the low coefficient of Dr. Banks, who succeeded Drs. Kennedy and Moore on November 1st, it must be borne in mind that the epidemic was then on its decline. The following table shows the number, and the coefficients of mortality and of recovery, of the patients under each of the physicians:—

The Physicians.	Admissions.	Deaths.	Recoveries.	Coefficient of Mortality per cent.
H. Kennedy, M.D.	79	37	42	46.83
W. Moore, M.D.	70	35	35	50.00
J. T. Banks, M.D.	31	13	18	41.61
Total ...	180	85	95	47.22

It only remains to notice the dimensions of the cholera wards:—

The Cholera Wards.	Height (in feet and inches.)	Length (in feet and inches.)	Breadth (in feet and inches.)	Number of cubic inches of air in each ward.	No. of beds in each ward.	Number of cubic inches of air to each patient.	Number of cubic feet* of air to each patient.
Female.	19'3"	37'3"	29'8"	36,759,492	8	4,594,936.5	2,659.10
Male.	20'1"	37'6"	29'6"	37,391,300	8	4,673,912.5	2,704.86

These wards, set apart at a time when the epidemic had not yet reached this city for those who might suffer from this disease, were each capable of containing 36,000,000 cubic inches of air. Each ward—that allotted to the females and that to the males—had eight occupants. Each of these, therefore, was allowed four and a-half million cubic inches, or two and a-half thousand cubic feet, of air. To this fact may be traced the good health of those who attended on the sufferers, and, in a great measure, the recoveries of those who suffered from the epidemic.

MATER MISERICORDIÆ HOSPITAL.

ABSTRACT OF REPORT ON CHOLERA.

By Dr. Hayden and Dr. Cruise.

DURING the prevalence of the late epidemic, 197 cases of cholera were treated in this hospital; of these a total of 106 proved fatal, and 91 recovered. Of cases in the first stage of cholera, or *Choleraic Diarrhœa* there were admitted 54, of these 52 recovered and 2 died.

Of cases in the second stage of cholera, or *collapse*, there were admitted 124, of these 85 died and 39 recovered.

These numbers do not include 19 cases which were

admitted in a moribund state, and beyond hope from treatment.

The following tables exhibit the foregoing statements in detail:—

TABLE I.

Week ending	No. of Cases.	Average duration of illness in hours.		Average period in Hospital, in hours.		Result.	Percentage of deaths.
		H.	M.	H.	M.

TABLE IV. A.

AGES OF PATIENTS WITHIN DECENNIAL PERIODS ADMITTED IN STAGE OF CHOLERAIC DIARRHœA—SUMMARY OF TREATMENT AND RESULT.

Age.	No. of cases.	TREATMENT.	Died.	Recovered.	Per centage.
Under 10 years	6	* Dilute sulphuric acid and opium, creasote-water. <i>ad libitum</i> . . . . .	...	6	
" 10 to 20	7	6 dilute sulph. acid and opium; 1 chalk mixture . . . . .	...	7	
" 20 " 30	19	12 do. do. in 1 this was preceded by a draught of castor oil, and in another it was followed by calomel given as stated below; 1 case got tinct. opium m x. in an ounce of brandy, calomel was then given, followed by bismuth and chlorodyne draughts; in 1 case a draught of oil with tinct. opii., and creasote-water for drink; in 4 cases purgatives were given, and 1 was treated expectantly . . . . .	...	19	
" 30 " 40	10	In 1 case acid and opium mixture with creasote, and external heat constituted the treatment; 4 acid and opium; 1 calomel and creasote; 2 chalk mixture; 1 expectant . . . . .	...	10	
" 40 " 50	4	In 1 tinct. opii., with nit. spirit ether and camph. mixture was given, preceded by draught of c. oil; in 1 oil draught followed by calomel in usual doses; 1 chalk mixture; 1 acid astringent do. . . . .	1	3	3.7
" 50 " 60	2	Acid astringent mixture . . . . .	...	2	
" 60 " 70	4	1 acid astringent mixture; 1 calomel followed by bismuth, chlor. ether, and tinct. opii. in camphor mixture; 2 chalk mixture . . . . .	1	3	
" 70 " 80	2	1 chalk mixture; 1 spir. am. aromat. with laudanum . . . . .	...	2	
Total...	54				

\* The mode of administration of sulphuric acid was usually as follows:—10 to 15 drops or more of the dilute, or of the sulphuric acid and with 5 drops of laudanum, and frequently 5 drops of tincture of capsicum, myrrh, or camphor, in an ounce of water, given after each evacuation.

TABLE IV. B.

AGES OF PATIENTS WITHIN DECENNIAL PERIODS ADMITTED IN STAGE OF COLLAPSE (*Algid Cholera*): SUMMARY OF TREATMENT AND RESULT.

Age.	No. of cases.	TREATMENT.	Died.	Recovered.	Per centage.
Under 10 years	26	21 calomel, in 3 of which concentrated solution of camphor was likewise given, and in 2 of them also inhalations of the nitrite of amyl; in 1 the warm bath; 4 diffusible stimulants, and in 1 of them also amyl inhalations; 1 arsenic; sinapisms and creasote-water	15	11	12.1
„ 10 to 20	19	13 calomel, and in 2 of these bismuth, &c., draughts; 2 quinine (1 with chloric ether); 2 stimulants; 4 diffusible stimulants, with effervescents; 1 digitalis, with spirit of juniper and nit. sp. of ether	7	12	5.64
„ 20 „ 30	25	21 calomel (in 4 preceded by dose of castor oil), and in 9 of these bismuth and chlorodyne, draughts, &c.; oxygen inhalations in 2 cases, and n. amyl in 1; venesection in 1; 2 got diffu. stim. and effervescents; 1 belladonna and permanganate of potass; and 1 arsenic,	17	8	13.7
„ 30 „ 40	19	15 calomel, with sinapisms, heat, and friction; of these 3 got brandy, 1 spt. camphor, and 1 amyl inhalations; 1 permang. potass.; 1 hyposulphite of soda, with digitalis and dry cupping; 2 stimulants,	16	3	12.9
„ 40 „ 50	20	14 calomel, and in 5 of these bismuth, creasote, and morphia also, after each dose of calomel; camphor in 2; amyl inhal. in 1, and oxygen do. in 1; castor-oil before the calomel in 2; in 2 digitalis, with n. s. ether; and in 2 stimulants	16	4	12.9
„ 50 „ 60	10	9 calomel; in one of these bismuth draughts; 1 hyposulph. sodæ; and in 1 oxygen inhalations	10	0	8.0
„ 60 „ 70	3	2 diffusible stimulants; 1 calomel	2	1	1.61
„ 70 „ 80	2	2 calomel; in 1 of these diffusible stimulants also	2	0	1.61
Total ...	124		85	39	68.5

Calomel was given as follows—viz., gr. x. were given at once, and subsequently gr. ii. every hour. In the case of children, the doses were reduced in proportion to the age. In the event of the stomach rejecting the calomel, a draught, consisting of liquor. bismuth. with chlorodyne, was given after each dose. In cases in which the stomach still continued to reject the mercurial in this form, it was administered by inunction or suppository. The drink given was creasote water (m. iii. to a pint of water) *ad libitum*. The nitrite of amyl was administered by inhalation in several cases, with the result of a slight but temporary elevation of temperature; oxygen was likewise similarly given in some cases, but with no marked beneficial result.

POST-MORTEM APPEARANCES IN COLLAPSE.

*General condition of body*—The post-mortem rigidity of very short duration; lividity less marked than before death; in some cases temperature raised.

*Cerebro-spinal system*—Cerebral veins and sinuses engorged with dark liquid blood; in cerebral ventricles and subarachnoid spaces, a small quantity of clear serum; puncta cruenta large and numerous; spinal cord and membranes normal.

*Ganglionic system*—Solar plexus and simular ganglia normal.

*Thorax*—Lungs congested but still crepitant; right cavities of heart filled with dark uncoagulated blood; left auricle and ventricle contracted and empty. The latter much reduced in size, and its walls thickened.

*Abdomen*—Liver, spleen, and kidneys normal; peritoneal investment of viscera white and polished; mesenteric glands considerably enlarged. Stomach containing a small quantity of gruel like fluid; mucous lining of vesophagus prolapsed into stomach, and presenting the appearance of wet parchment; mucous lining of stomach, mamillated; intestinal canal nearly filled with a fluid like thin boiled starch mixed with white foci. Brunner's glands enlarged; both solitary and agminate glands enlarged and filled to distension with opaque fluid; mucous lining vas-

cular in jejunum and upper part of ileum; towards termination of ileum Payer's patches were in a state of erosion, the contents of the glandules having escaped through small apertures, visible on the surface. The fluid contents of the glandules, examined under the microscope, were found to consist of large granule cells, and amorphous granular matter.

*Larynx*—Vocal cords thickened and ventricles reduced in size, but without vascularity.

*Diffusion of Cholera*—In no instance did the disease spread in the Hospital, although, during the whole continuance of the epidemic, many were fully exposed. Of these we may especially mention the Sisters in charge of the wards—the Medical Officers, the clinical clerks—the class—the ward maids and porters engaged in carrying up the sick and removing the dead. One woman, in one of the general wards, took cholera and died; upon full investigation the origin of her case was clearly traced to an infected lodging-house in which she had stopped previous to entering the Hospital.

*Disinfection, Ventilation, &c.*—The *excreta* of the patients were promptly disinfected by means of chloride of lime and carbolic acid. Thorough ventilation was scrupulously attended to. The patients generally had a breathing space of more than 2000 cubic feet.

50	50	50	[illegible]	[illegible]

[The following text is extremely faint and largely illegible. It appears to be a series of entries or a detailed report, possibly containing names, dates, and descriptions. The text is organized into columns, similar to the table above, but the individual characters are too light to transcribe accurately.]
